Chapter I. Representations

1. The groups that we will treat in detail

Let $K$ be a field. The basic groups are

\[ GL(n, K) = \{ A \in K^{n \times n}; \; \text{det} A \neq 0 \}, \]
\[ SL(n, K) = \{ A \in K^{n \times n}; \; \text{det} A \neq 0 \}, \]

in particular

\[ SL(2, \mathbb{R}), \; SL(2, \mathbb{C}). \]

We denote by $E_p$ the $p \times p$ unit-matrix and by

\[ E_{pq} = \begin{pmatrix} -E_q & 0 \\ 0 & E_p \end{pmatrix}. \]

The orthogonal groups are

\[ O(p, q) = \{ A \in GL(n, \mathbb{R}); \; A^t E_{pq} A = E_{pq} \}, \; p + q = n \]
and the unitary groups are

\[ U(p, q) = \{ A \in GL(n, \mathbb{C}); \; A^* E_{pq} A = E_{pq} \}, \; p + q = n \]

Their subgroups of determinant 1 are denoted by $SO(p, q)$ and $SU(p, q)$ will be studied in detail. In the case $p = 0$ we omit $p$ in the notation, $O(q) = O(0, q) \ldots$

The main examples we will treat are

\[ SO(2, \mathbb{R}) \subset SL(2, \mathbb{R}), \; SU(2, \mathbb{C}) \subset SL(2, \mathbb{R}). \]

We will occur some exceptional isomorphisms. Let $S^1$ be the group of complex numbers of absolute value one. Obviously

\[ S^1 = U(1). \]
There is also the isomorphism
\[
\text{SO}(2, \mathbb{R}) \sim \sim S^1, \quad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \mapsto a + ib.
\]

The *Lorentz group* is $O(3, 1)$. It contains two subgroups of index two. One is $\text{SO}(3, 1)$, the other can be defined through
\[
O^+(3, 1) = \{ A \in O(3, 1); \ a_{11} > 0 \}.
\]
(We will see that this is actually a group). The intersection
\[
\text{SO}^+(3, 1) = O^+(3, 1) \cap \text{SO}(3, 1)
\]
is a subgroup of index 4 of the Lorentz group. This subgroup is closely related to the group $\text{SL}(2, \mathbb{C})$. We will construct a surjective homomorphism
\[
\text{SL}(2, \mathbb{C}) \rightarrow \text{SO}^+(3, 1)
\]
such that each element of $\text{SO}^+(3, 1)$ has two pre-images which differ only by the sign. One says that $\text{SL}(2, \mathbb{C})$ is a twofold covering of $\text{SO}^+(3, 1)$ and one calls this the spin covering and uses the notation $\text{Spin}(3, 1) = \text{SL}(2, \mathbb{C})$.

The group $O(3)$ can be embedded into the Lorentz group $O(3, 1)$ by means of
\[
A \mapsto \begin{pmatrix} 1 & 0 \\ 0 & A \end{pmatrix}.
\]
It is contained in $O^+(3, 1)$, hence $\text{SO}(3)$ occurs as subgroup of $\text{SO}^+(3, 1)$. It turns out that the subgroup $\text{SU}(2) \subset \text{SL}(2, \mathbb{C})$ maps onto $\text{SO}(3)$. Hence
\[
\text{SU}(2) \rightarrow \text{SO}(3)
\]
is also a surjective homomorphism such that each element of the image has exactly two pre-images which differ by a sign. This should be considered again as a spin covering, so the notation $\text{Spin}(3) = \text{SU}(2)$ looks natural.

The group $O(3, 1)$ is also called the *homogeneous Lorentz group*. The *inhomogeneous Lorentz group* is the set of all transformations of $\mathbb{R}^4$ of the form
\[
v \mapsto A(v) + b
\]
where $A$ is a Lorentz transformation and $b \in \mathbb{R}^4$. This group can be identified with the set $O(3, 1) \times \mathbb{R}^4$. The group law then is
\[
(g, a)(h, b) = (gh, a + gb).
\]
We write for the inhomogeneous Lorentz group simply

\[ O(3, 1) \mathbb{R}^4. \]

A variant of the inhomogeneous Lorentz group is the Poincaré group \( P(3) \). As set it is

\[ P(3) = \text{SL}(2, \mathbb{C}) \times \mathbb{R}^4 \]

and the group law is

\[ (g, a)(h, b) = (gh, a + gb). \]

There is a natural homomorphism \( P(3) \to \text{SO}^+(3, \mathbb{R}) \mathbb{R}^4 \). It is a twofold covering in the obvious sense.

## 2. Generalities about Banach- and Hilbert spaces

Usually, we consider only vector spaces over the field of real or complex numbers. If \( E, F \) are two vector spaces, we denote by \( \text{Hom}(E, F) \) the space of all (real- or complex-) linear maps. In the case \( E = F \) we write \( \text{Hom}(E, E) = \text{End}(E) \). The group of all invertible operators in \( \text{End}(E, E) \) is denoted by \( \text{GL}(E) \).

A norm on a vector space \( E \) is a real valued function \( \| \cdot \| \) on \( E \) with the properties \( \| a \| \geq 0 \) and \( = 0 \) only for \( a = 0 \), \( \| C a \| = |C| \| a \| \), \( \| a + b \| \leq \| a \| + \| b \| \) \((a, b \in E), C \in \mathbb{C} \) (or \( \mathbb{R} \)). Then \( \| a - b \| \) is a metric on \( E \). The normed space \( E \) is called complete, or a Banach space, if every Cauchy sequence converges. Every normed space \( E \) can be embedded into a Banach space \( \bar{E} \) as a dense subspace (with the restricted norm) in an essentially unique manner. One calls \( \bar{E} \) the completion of \( E \). Let \( F \subset E \) be a linear subspace of a Banach space. It is a closed subspace if and only if it is a Banach space (with respect to the
restricted norm). The closure of a linear subspace in a Banach space is a linear subspace and hence a Banach space. It can be identified with its completion. Since any two norms on a finite dimensional vector space are equivalent, every finite dimensional normed vector space is a Banach space. As a consequence, every finite dimensional subspace of a normed vector space is closed.

A linear map \( A : E \to F \) between normed vector spaces is called *bounded* if there exists a constant \( C \geq 0 \) such that \( \|Aa\| \leq C\|a\| \) for all \( a \in E \). Then there exists a smallest number \( C \) with this property. It is called the norm of \( A \) and is denoted by \( \|A\| \). We mention that \( A \) is bounded if and only if it is continuous (at the origin is enough). For finite dimensional \( E, F \) each linear map is bounded. Let \( E \) be a normed space and \( F \) be a Banach space. The subspace of all bounded operators

\[ B(E, F) \subset \text{Hom}(E, F) \]

of \( \text{Hom}(E, F) \) is a Banach space (equipped with the operator norm). We use the abbreviation

\[ B(E) = B(E, E). \]

If \( F \) is the ground field (\( \mathbb{R} \) or \( \mathbb{C} \)) then \( E' = B(E, F) \) is the so called dual space.

An imported theorem on Banach spaces is the open mapping theorem. It states that any any linear bounded and surjective operator \( f : E \to F \) of Banach spaces is open, i.e. the image of an open subset is open. In particular a bijective linear bounded operator \( f : E \to F \) has the property that its inverse is automatic bounded, hence an invertible element in \( B(E) \). A consequence of this is the closed graph theorem. It states that a linear map \( f : E \to F \) between Banach spaces is bounded if an only if the graph \( \{ (x, f(x)) ; x \in E \} \) is a closed subset of \( E \times F \) (equipped with the product topology).

All what we have said so far about Banach spaces can be formulated and is true for real and complex Banach spaces. Now we consider complex vector spaces.

A Hermitian form on a complex vector space \( E \) is a function \( \langle \cdot, \cdot \rangle : E \times E \to \mathbb{C} \) which is linear in the first variable and which has the property \( \langle a, b \rangle = \langle b, a \rangle \). It is called positive definite if \( \langle a, a \rangle > 0 \) for all \( a \neq 0 \). Then \( \|a\| := \sqrt{\langle a, a \rangle} \) is norm. We call \( (E, \langle \cdot, \cdot \rangle) \) a Hilbert space if it is a Banach space with this norm.

We will make use of the Theorem of Riesz:

*Let \( L : H \to \mathbb{C} \) be a continuous linear functional on a Hilbert space \( H \). Then there exists a unique vector \( a \in H \) such that \( L(x) = \langle x, a \rangle \) (and each linear functional of this kind is continuous and has the norm \( \|L\| = \|a\| \)).*

These special linear forms show that for every vector \( a \in H, a \neq 0 \), there exists a continuous linear functional \( L \) with the property \( L(a) \neq 0 \).

This statement is also true for Banach spaces. From the theorem of Hahn-Banach follows the following result:
For each non-zero vector \( a \in E \) of a Banach space there exists a continuous linear functional \( L \) with the property \( L(a) \neq 0 \).

We will make use of another important result about Hilbert spaces. Let \( A \subset H \) be a closed linear subspace. Denote by

\[
B = \{ b \in H; \langle a, b \rangle = 0 \text{ for all } a \in A \}
\]

the orthogonal complement of \( A \). This is a closed linear subspace and one has \( H = A \oplus B \).

A family \( (a_i)_{i \in I} \) is called an orthonormal system if any two members with different indices are orthogonal and if the norm of each member is one. A Hilbert space basis of a Hilbert space is by definition a maximal orthonormal system. It is easy to show (using Zorn’s lemma and the above remark about orthogonal complements) that Hilbert space bases exist. Even more, every orthonormal system is contained in a maximal one.

A Hilbert space \( H \) is called separable if it contains a countable dense subset. One can show that this is the case if and only if each Hilbert space basis is finite or countable.

We recall some basics about infinite series. A series \( a_1 + a_2 + \cdots \) in a Banach space \( E \) is called convergent if there exist \( a \) such that

\[
\| a - \sum_{\nu=1}^{n} a_{\nu} \| \to 0 \quad \text{for } n \to \infty.
\]

A sufficient condition is that \( \sum \| a_{\nu} \| \) converges. But this condition is not necessary.

In the special case that \( E = H \) is a Hilbert space and that the \( a_i \) are pairwise orthogonal one can show the following. The series converges if and only if \( \sum \| a_{\nu} \|^2 \) converges.

We give an example of a separable Hilbert space. The space \( \ell^2 \) consists of all sequences \((a_1, a_2, \ldots)\) of complex numbers such that \( \sum |a_n|^2 \) converges. It can be shown that for two \( a, b \in \ell^2 \) the series

\[
\langle a, b \rangle = \sum a_n \overline{b_n}
\]

converges absolutely and equips \( \ell^2 \) with the structure as a Hilbert space. The usual unit vectors (1 at one place and 0 at the others) give a Hilbert space basis.

Let now \( H \) be any infinite dimensional separable Hilbert space with a Hilbert space basis \( e_1, e_2, \ldots \). For each \( a \in \ell^2 \) the series

\[
\sum_{n=1}^{\infty} a_n e_n := \lim_{N \to \infty} \sum_{n=1}^{N} a_n e_n
\]
then converges in \( H \). This gives a map

\[
\ell^2 \xrightarrow{\sim} H.
\]

This map is actually an isomorphism of Hilbert spaces (which means that it is an isomorphism of vector spaces which preserves the Hermitian forms). Hence all infinite dimensional separable Hilbert spaces are isomorphic as Hilbert spaces. (The same kind of argument shows a standard result of linear algebra, namely that two finite dimensional Hilbert spaces are isomorphic as Hilbert spaces if and only if their dimensions agree.)

Assume that \( H_1, H_2, \ldots \) is a sequence of pairwise orthogonal closed subspaces of the Hilbert space \( H \). Assume that their algebraic sum is dense in \( H \). If we choose a Hilbert space basis in each \( H_i \) and collect them, we get a Hilbert space basis of \( H \). This shows that every \( a \in H \) has a unique representation as convergent series \( a = a_1 + a_2 + \cdots \) where \( a_i \in H_i \). Recall that this means that \( \sum\|a_i\|^2 \) converges. We write this as

\[
H = \bigoplus_i H_i
\]

and call this a direct Hilbert sum.

There is an abstract version of this. Let \( H_n \) be a family of Hilbert spaces. We define \( H \) to be the set of all sequences \( (h_n) \), \( h_n \in H_n \) such that \( \sum\|h_n\|^2 \) converges. There is a natural imbedding of \( H_n \) into \( H \). The image \( \tilde{H}_n \) consists of all elements of \( H \) such only the \( n \)th component can be different from 0. The space \( H \) carries a natural structure as Hilbert space and it is the direct Hilbert of the \( \tilde{H}_n \). Usually one identifies \( \tilde{H}_n \) with \( H_n \) and calls \( H \) the direct Hilbert sum of the \( H_n \).

3. Generalities about measure theory

All topological spaces that carry measures are assumed to be Hausdorff, locally compact and to have a countable basis of the topology. The latter means that there exists a countable system of open subsets such that each open subset can be written as a union of sets from this system. Every metric space with an countable dense subset (for example \( \mathbb{C}^n \)) has this property. Every subspace (equipped with the induced topology) keeps this property.

We denote by \( \mathcal{C}(X) \) the set of complex valued continuous functions on a locally compact space \( X \) and by \( \mathcal{C}_c(X) \) the subset of all continuous functions with compact support. A Radon measure is a linear functional \( I : \mathcal{C}_c(X) \to \mathbb{R} \) which is real in the sense \( I(f) = \overline{I(f)} \) and positive in the sense that \( I(f) \geq 0 \).
for real $f \geq 0$. Usually one writes

$$I(f) = \int_X f(x) \, dx.$$ 

We assume that the reader is familiar with some way to extend a Radon measure to the class of integrable functions. We just indicate the steps, how this can be done.

One introduces $\mathbb{R} \cup \{\infty\}$ as ordered set ($x \leq \infty$ for all $x$). Every non-empty set $M \subset \mathbb{R} \cup \{\infty\}$ has a smallest upper bound $\text{Sup}(M)$ in $\mathbb{R} \cup \{\infty\}$. One extends the addition to $\mathbb{R} \cup \{\infty\}$ by $x + \infty = \infty + x$ for all $x$ and similarly the multiplication with a positive $C > 0$ by $C \infty = \infty C$.

A function $f : X \to \mathbb{R} \cup \{\infty\}$ is called a Baire function, if there exists an increasing sequence $f_n \in \mathcal{C}_c(X)$, $f_1 \leq f_2 \leq \ldots$ such that $f(x) = \text{Sup}\{f_n(x) ; x \in X\}$. One can show that

$$I_B(f) := \text{Sup}\{I(f_n)\}$$

is independent of the choice of the sequence. Every $f \in \mathcal{C}_c(X)$ is a Baire function and in this case $I_B(f)$ agrees with $I(f)$. We mention that the function “constant $\infty$” is a Baire function. Hence we can define for an arbitrary nowhere negative function $f : X \to \mathbb{R} \cup \{\infty\}$

$$\bar{I}(f + g) \leq \bar{I}(f) + \bar{I}(g)$$ holds.

Now one can define integrable functions:

A function $f : X \to \mathbb{R}$ is called integrable if there exists a sequence $f_n \in \mathcal{C}_c(X)$ such that $\bar{I}(|f - f_n|)$ is finite and tends to zero.

One can show that then $(I(f_n))$ converges and that the limit

$$I_L(f) = \lim_{n \to \infty} I(f_n)$$

is independent of the choice of $f_n$. This is called the integral of $f$. One can show even more that Baire functions $f$ with finite $I_B(f)$ (for example elements of $\mathcal{C}_c(X)$) are integrable and that $I_L(f) = I_B(f)$ in this case. Hence we can simply write $I(f) = I_B(f)$ for Baire functions and $I(f) = I_L(f)$ for integrable functions. $I(f) = I(f)$ for integrable $f$. It is easy to see that the space $L^1(X, dx)$ of all integrable functions is a vector space. It has the property that with $f$ also $|f|$ is integrable. The integral is a linear functional on $L^1(X, dx)$ with the property $I(f) \geq 0$ for $f \geq 0$.

A function $f : X \to \mathbb{C}$ is called a zero function if $\bar{I}(|f|) = 0$. This means that for each $\varepsilon > 0$ there exists a Baire function $h$ with $|f| \leq h$ and $I(h) < \varepsilon$. It is easy to see that zero functions are integrable. A subset of $X$ is called a zero subset if its characteristic function is a zero function. A function $f$ is a zero function if an only if $\{x; f(x) \neq 0\}$ is a zero set. If $f$ is integrable and $g$ is a function that coincides with $f$ outside a zero set then $g$ is integrable too and $I(f) = I(g)$.

We recall the basic limit theorems:
3.1 Theorem of Beppo Levi. Assume that $f_1 \leq f_2 \ldots$ is an increasing sequence of integrable functions such that the sequence of their integrals is bounded in $\mathbb{R}$. Then the pointwise limit $f(x) = \lim_{n \to \infty} f_n(x)$ exists outside a zero set. If one defines $f(x)$ arbitrarily for this zero set, one gets an integrable function with the property

$$\int_X f(x)dx = \lim_{n \to \infty} \int_X f_n(x)dx.$$  

3.2 Lebesgue’s limit theorem. Let $f_n(x)$ be a pointwise convergent sequence of integrable functions. Assume that there exists an integrable function $h$ with the property $|f_n(x)| \leq h(x)$ for all $n$ and $x$. Then $f(x) = \lim f_n(x)$ is integrable and one has

$$\int_X f(x)dx = \lim_{n \to \infty} \int_X f_n(x)dx.$$  

The subset $\mathcal{N} \subset L^1(X, dx)$ of zero functions is a sub-vector space and the integral factors through the quotient

$$L^1(X, dx) := L^1(X, dx)/\mathcal{N}.$$  

From the limit theorems one can deduce that this space gets a Banach space with the norm

$$\|f\|_1 := \sqrt{\int_X |f(x)|dx}.$$  

Let $(f_n)$ be a sequence in $L^1(X, dx)$ and $f \in L(X, dx)$. Assume that $f_n \to f$ in the Banach space $L^1(X, dx)$. (Usually we will denote the class of an element $f \in L^1(X, dx)$ in $L(X, dx)$ by the same letter $f$. A more careful notation would be to use a notation like $[f]$ for the class. For sake of simplicity we avoid this as long it is clear whether we talk of $f$ or of its class.) Then one can show that there exists a zero set $S$ and a subsequence of $(f_n)$ that converges pointwise to $f$. (This is the essential step in the proof that $L^1(X, dx)$ is a Banach space.  

Let us assume that the Radon measure is non-trivial in the following sense: Let $f \in C_c(X)$ be a non-negative function with the property $I(f) = 0$. Then $f = 0$. For such a measure the natural map

$$C_c(X) \to L^1(X, dx)$$

is injective and $L^1(X, dx)$ is the completion of $C(X)$ with respect to the norm $\| \cdot \|_1$. Hence integration theory can be understood as a concrete realization of the completion.
There is another important notion:

A function \( f : X \to \mathbb{C} \) is called \textbf{measurable} if for any non-negative function \( h \in \mathcal{C}_c(X) \) the function

\[
    f_h(x) := \begin{cases} f(x) & \text{if } -h(x) \leq f(x) \leq h(x), \\ 0 & \text{else} \end{cases}
\]

is integrable.

Integrable functions are measurable. All continuous functions are measurable. Measurability is conserved under all kind of standard constructions of functions which are used in analysis as addition and multiplication of functions but also taking pointwise limits and constructions as sup, inf, lim sup, lim inf for sequences of functions. A subset of \( X \) is called measurable if its characteristic function is measurable. Open subsets of \( X \) are measurable. Complements of measurable sets are measurable. Countable unions and intersections of measurable sets are measurable. Hence all sets which can be constructed from open and closed subsets be taking countable unions and intersections and complements are measurable with respect to each Radon measure. (They are called Borel sets.) So the statement “all functions are measurable” is not really true but nearly true. (Counter examples need sophisticated application of the axiom of choice.)

**3.3 Theorem.** A function \( f \) is integrable if and only if it is measurable and if \( \bar{I}(|f|) < \infty \).

Together with the previous remark this means that integrability means a kind of boundedness.

Let \( p \geq 1 \). The spaces \( \mathcal{L}^p(X, dx) \) consist of all measurable functions \( f \) such that \( |f|^p \) is integrable. This is the case for zero functions. One defines

\[
    \|f\|_p := \left( \int_X \left( \int_X |f|^p \right)^{\frac{1}{p}} dx \right)^{\frac{1}{p}}.
\]

This satisfies the triangle inequality. It induces a norm on the space

\[
    L^p(X, dx) = \mathcal{L}^p(X, dx)/\mathcal{N}
\]

which is a Banach space with this norm. The case \( p = 2 \) is of special importance. One can consider on \( \mathcal{L}^2(X, dx) \) the Hermitian form

\[
    (f, g) := \int_X f(x) \overline{g(x)} dx.
\]

This induces a positive definite form on \( L^2(X, dx) \) and equips this space with a structure as separable Hilbert space.
As a special example one can take the space $X = \mathbb{N}$ equipped with the discrete topology and the Radon measure $I(a) = \sum_n a_n$. The associated $L^2$-space is $\ell^2$.

There is an extension of measure theory, the Bochner integral. For a Banach space $E$ we can consider the space of compactly supported continuous functions $C_c(X, E)$ with values in $E$.

**3.4 Lemma.** Let $(X, dx)$ be a Radon measure and $E$ a Banach space. There exists a unique linear map

$$C_c(X, E) \to E, \quad f \mapsto \int_X f(x)dx,$$

such that for each continuous linear functional $L : E \to \mathbb{C}$ one has

$$L\left(\int_X f(x)dx\right) = \int_X L(f(x))dx.$$

The uniqueness follows directly from the Hahn-Banach theorem. So the existence, but not so quite obvious. Since for our purposes it would be sufficient to treat the case of Hilbert spaces we mention that the existence in this case is a direct consequence of the Theorem of Riesz.

There is also the notion of a measurable function. We only need it in the case where $E$ is separable which means that it contains a countable dense subset. Then a function $f : X \to E$ is measurable if and only if its composition with all continuous linear forms is measurable. A measurable function $f : X \to E$ is called a zero function if it is zero outside a zero set. Now the spaces $L^p(X, E, dx)$ can be defined in the same way as in the case $E = \mathbb{C}$. They contain the space $\mathcal{N}$ of zero functions and the quotients $L^p(X, E, dx)$ are Banach spaces. If $E = H$ is a Hilbert space, the space $L^2(X, H, dx)$ gets a Hilbert space with an obvious inner product.

Finally we mention the notion of the product measure. Let $(X, dx), (Y, dy)$ be two locally compact spaces with Radon measures. We consider $X \times Y$ equipped with the product measure. This also locally compact space. Let $f \in C_c(X \times Y)$. If we fix $y$ we get a function $f(x, y)$ which is contained in $C_c(X)$. It is easy to see that the integral $\int f(x, y)dy$ is contained in $C_c(Y)$. Hence we can define the product measure

$$\int_{X \times Y} f(x, y)dx dy := \int_Y \left[ \int_X f(x, y)dx \right] dy.$$

We claim that one can interchange the orders of integration, i.e.

$$\int_Y \left[ \int_X f(x, y)dx \right] dy = \int_X \left[ \int_Y f(x, y)dy \right] dx.$$
This is trivial for splitting functions $f(x,y) = \alpha(x)\beta(y)$ and follows in general by means of the Weierstrass approximation theorem. The formula

$$\int_{X \times Y} f(x,y) \, dx \, dy = \int_Y \left[ \int_X f(x,y) \, dx \right] \, dy = \int_X \left[ \int_Y f(x,y) \, dy \right] \, dx$$

extends to a broader class of functions and is then called Fubini’s theorem. One has to assume that $f \in L^1(X \times Y, dx \, dy)$. But one has to be somewhat cautious with the interpretation of the formula. One only can say that the function $y \mapsto f(x,y)$ is integrable outside a set of measure zero. Inside this exceptional set one can take for $\int_X f(x,y) \, dy$ an arbitrary value, for example 0.

There is a variant, the theorem of Tonelli. Assume that $f$ is measurable and that the iterated outer integral $\int_Y \int_X f(x,y) \, dx \, dy$ is finite. Then $f$ is integrable (and the Fubini formula holds).

### 4. Generalities about Haar measures

A topological group $G$ is a group which carries also a topology such that the maps

$$G \times G \rightarrow G, \quad (g,h) \mapsto gh, \quad G \rightarrow G, \quad g \mapsto g^{-1},$$

are continuous. Here $G \times G$ has been equipped with the product topology. A **locally compact group** is a topological space whose underlying space is locally compact. We always assume that $G$ has a countable basis of the topology.

Examples of locally groups are $\text{GL}(n, \mathbb{C})$. One just takes the induced topology of $\mathbb{C}^{n \times n}$. Closed subgroups of a locally group are locally compact groups as well. Hence $\text{SL}(n, \mathbb{C})$, $\text{GL}(n, \mathbb{R})$, $\text{SL}(n, \mathbb{R})$, $\text{O}(p,q)$, $\text{U}(p,q)$ are locally compact groups. Also the additive groups $\mathbb{R}^n$, $\mathbb{C}^n$ and the inhomogeneous Lorentz group and the Poincaré group $P(3) = \text{SL}(2, \mathbb{C}) \cdot \mathbb{R}^4$ are locally compact groups. (Take the product topology.)

A Haar measure on a locally compact group $G$ is a non-zero left invariant Radon measure

$$\int_G f(x) \, dx = \int_G f(gx) \, dx \quad (g \in G).$$

We make use of the fact that a non zero Haar measure always exists and is uniquely determined up to a constant factor.

The usual integral on $\mathbb{R}$ is a Haar measure on the additive group $\mathbb{R}$ and a Haar measure on the multiplicative group $\mathbb{R}^*$ is given by

$$\int_{\mathbb{R}} f(t) \frac{dt}{t}$$

where $dt$ is the usual measure.
If \( f \in C_c(G) \) is a function with the properties \( f \geq 0 \) and \( I(f) = 0 \). Then \( f = 0 \). Hence we have \( C_c(G) \hookrightarrow L^p(G, dx) \).

Let \( g \in G \). Then
\[
\int_G f(xg) dx
\]
is also left invariant. Hence there exists a positive real number \( \Delta(g) = \Delta_G(g) \) with the property
\[
\int_G f(xg^{-1}) dx = \Delta(g) \int_G f(x) dx.
\]
The function \( \Delta : G \to \mathbb{R}_{>0} \) is of course independent of the choice of \( dx \). It is called the modular function of \( G \). It is clearly a continuous homomorphism, \( \Delta(gh) = \Delta(g)\Delta(h) \).

4.1 Lemma. For every function \( f \in L^1(G, dx) \) the formula
\[
\int_G f(x^{-1})\Delta(x^{-1}) dx = \int_G f(x) dx
\]
holds.

Proof. One can check that the integral on the left hand side is a Haar measure. Hence it agrees with the right hand side up to constant a factor \( C > 0 \). Applying the formula twice we get \( C^2 = 1 \) and hence \( C = 1 \).

The group \( G \) is called unimodular if \( \Delta(g) = 1 \) for all \( g \). There are three obvious classes of unimodular groups:
1) Abelian groups are unimodular.
2) A group \( G \) is unimodular if its commutator subgroup is dense.
3) Compact groups are unimodular, more generally, for arbitrary \( G \) the restriction of \( \Delta_G \) to any compact subgroup is trivial.
3) Discrete groups are unimodular.

The last statement is true since the only compact subgroup of the multiplicative group of positive reals is \{1\}.

We give an example of a group which is not unimodular. Let \( P \subset SL(2, \mathbb{R}) \) be the group of all upper triangular matrices of determinant 1. Each \( p \) can be written in the form
\[
p = \begin{pmatrix} a & 0 \\ 0 & a^{-1} \end{pmatrix} \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix} \quad (a \neq 0).
\]

Moreover the map
\[
\mathbb{R}^* \times \mathbb{R} \xrightarrow{\sim} P, \quad (a, n) \mapsto p,
\]
is topological. Hence we can identify \( C_0(P) \) and \( C_c(\mathbb{R}^* \times \mathbb{R}) \).
4.2 Lemma. Let $P \subset \text{SL}(2, \mathbb{R})$ be the group of upper triangular matrices. Let $da$ be a Haar measure on $\mathbb{R}$ and $dn$ a Haar measure on $\mathbb{R}$. Then the measure
\[ \int_P f(p) dp := \int_{\mathbb{R}} \int_{\mathbb{R}} f(an) da \, dn \]
is a Haar measure. The modular function is \[ \Delta(p) = a^2. \]
(One can also write $\int \int f(an) \, dn \, dn$ for the right hand side, since orders of integration can be interchanged, but $\int \int f(na) \, da \, dn$ would be false.)

Proof. The proof can be given by a simple calculation which rests on the formula
\[ \begin{pmatrix} a & 0 \\ 0 & a^{-1} \end{pmatrix} \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix} \begin{pmatrix} a^2 & 0 \\ 0 & a^{-1} \end{pmatrix}. \]
We also need quotient measures. Let $H \subset G$ be a closed subgroup of a locally compact group $G$. Then $H$ is also locally compact. We consider the coset space $H \backslash G$ that consists of all right cosets $Hg$. This is the quotient space of $G$ by the natural action of $H$ (multiplication from the right.) We equip it with the quotient topology with respect to the natural projection $G \rightarrow H \backslash G$. Then this projection is continuous and open. We claim that $H \backslash G$ is Hausdorff. Hausdorff means that the diagonal in $H \backslash G \times H \backslash G$ is closed. This means that its inverse image in $G \times G$ is closed. But this inverse image of $H$ with respect to the map $G \times G \rightarrow G$, $(x, y) \mapsto xy^{-1}$.

Since $G \rightarrow H \backslash G$ is open, the space $H \backslash G$ is locally compact. There is also a natural continuous map
\[ (H \backslash G) \times G \rightarrow H \backslash G, \quad (Hg_1, g_2) \mapsto Hg_1g_2 \]
which as action from the right. A Radon measure $dx$ on $X = H \backslash G$ is called $G$-invariant if
\[ \int_{H \backslash G} f(xy) dx = \int_{H \backslash G} f(x) dx. \]

4.3 Proposition. Let $H \subset G$ be a closed subgroup. Assume that $\Delta_G|H = \Delta_H$. Then there exists a non-zero invariant Radon measure $dy$ on $H \backslash G$ and this Radon measure is unique up to a positive constant factor. It has the following property. Let $dh$ be a right invariant Haar measure on $H$. Then
\[ \int_G f(x) dx = \int_{H \backslash G} \left[ \int_H f(hy) dh \right] dy \]
is a right invariant measure on $G$.

We should mention that the function $y \mapsto \int_H f(yh) dh$ can be considered as a function on $H \backslash G$. It is continuous and with compact support there.

We indicate the general proof of the existence of an invariant measure. We formulate without proof a key lemma.
4.4 Lemma. The map
\[ C_c(G) \rightarrow C_c(H \backslash G), \quad f \mapsto f', \quad f'(y) = \int_H f(yh)dh, \]
is surjective.

For a function \( f' \) we define the integral \( \int_{H \backslash G} f(y)dy \) using the formula in Proposition 4.3 where on the left hand side a right invariant Haar measure is taken. There is a problem. The function \( f' \) does not determine \( f \) uniquely. Hence one has to prove a Lemma.

4.5 Lemma. Let \( f \in C_c(G) \). Then
\[ \int_H f(hy)dh = 0 \Rightarrow \int_G f(x)dx. \]

It is a good exercise to do this for a finite group \( G \). The integrals then just are finite sums. In the general case the condition \( \Delta_G \mid H = \Delta_H \) will play a role. We give the argument in some detail, since we want to weaken this condition later. There is a basic formula.

4.6 Lemma. Let \( dh, dx \) be right invariant Haar measures on \( H \) and \( G \). The condition \( \Delta_G \mid H = \Delta_H \) implies
\[ \int_G f'(x)g(x)dx = \int_G f(x)g'(x). \]

Proof. We consider the product measure \( dh \times g \) on \( H \times G \). Then we have
\[ \int_G f'(x)g(x) = \int_G \left[ \int_H f(hx)dh \right] g(x)dx = \int_{H \times G} f(hx)g(x)dhdg. \]

by Fubini’s theorem we can reverse the order of integration,
\[ \int_G f'(x)g(x) = \int_H \left[ \int_G f(hx)g(x)dx \right] dh. \]

In the inner integral we replace \( x \mapsto h^{-1}x \). By means of the assumption about the modular functions we finish the proof of the lemma.

In this way we get the existence of an invariant measure on \( H \backslash G \) such the claimed formula holds. The proof of the uniqueness of the quotient measure is the same as the proof of the uniqueness of the Haar measure.

We also mention that the formula in Proposition 4.3 holds for all \( f \in L^1(G, dx) \) with the usual caution: the inner integral exists outside of a set of measure zero and gives – extended arbitrarily – an integrable function on \( H \backslash G \).

Instead of \( H \backslash G \) one can also consider the space of left cosets \( G/H \) and \( G \) acts by multiplication from the left. Proposition 4.3 remains true if one replaces “right” by “left”. The two versions can be transformed into each other using the transformation \( g \mapsto g^{-1} \).
5. Generalities about representations

A representation $\pi$ of a group $G$ on a complex vector space is a homomorphism $\pi : G \to \text{GL}(V)$ of $G$ into the group of $\mathbb{C}$-linear automorphisms of $V$. Frequently we will write $g(a)$ or even simply $ga$ instead of $\pi(g)(a)$. The map

$$G \times V \longrightarrow V, \quad (g,a) \longmapsto ga,$$

then has the properties:

1) $ea = a$ for all $a \in V$ (e denotes the unit element of $G$).
2) $(gh)a = g(ha)$ for all $g, h \in G$, $a \in V$.
3) $g(a + b) = g(a) + g(b)$, $g(Ca) = Cga$ ($C \in \mathbb{C}$).

Conversely, a map with the properties 1)-3) comes from a unique representation $\pi$.

**Left and Right**

Let $G$ be a group and $V$ simply a set. A map

$$G \times V \longrightarrow V, \quad (g,a) \longmapsto ga,$$

with the properties 1)-2) is also called an action of $G$ from the left on $V$. If one replaces in 2) the condition by $(gh)a = h(g(a))$ one gets the notion of an action from the right. This looks better if one uses the notation $ag$ instead of $ga$ since then the rule takes the better looking form $a(gh) = (ag)h$. If $ga$ is an action from the left then $g^{-1}a$ is an action from the right, and conversely. Hence there is no essential difference between the two. Keep in mind that due to our definition representations are actions from the left.

**Continuous representations**

There are several equivalent ways to define when a representation of a locally compact group on a Banach space is continuous. A natural way is as follows.

**5.1 Definition.** A representation of a locally compact group $G$ on a Banach space is called continuous if the corresponding map

$$G \times E \longrightarrow E$$

is continuous.

Here $G \times E$ of course carries the product topology. For a continuous representation the operators $\pi(g) : E \to E$ are continuous (hence bounded) and the map $G \to E, g \mapsto g(a)$, is continuous for each $a \in E$. The converse is also true.
5.2 Proposition. A representation $\pi$ of a locally compact group $G$ on a Banach space $E$ is continuous if all operators $\pi(g) : E \to E$ are bounded and if the map

$$G \to E, \ g \mapsto \pi(g)(a),$$

is continuous for all $a \in E$.

The proof rests on the theorem of uniform boundedness:

5.3 Theorem. Let $E$ be a Banach space and let $\mathcal{M} \subset B(E)$ be a set of bounded operators such that $\{Aa, a \in E\}$ is bounded for each $a \in E$. Then $\mathcal{M}$ is a bounded subset of $B(E)$.

We omit the prove.

For the proof of Proposition 5.2 we need another observation.

5.4 Lemma. Let $\pi : G \to \text{GL}(E)$ be a continuous representation and $K \subset G$ a compact subset. Then the set $\pi(K)$ is bounded in $B(E)$.

Proof. Since $\pi(K)a$ is compact and hence bounded for all $a$, the theorem of uniform boundedness gives the claim.

Proof of Proposition 5.2. It is sufficient to prove the $\pi : G \times E \to E$ is continuous at a point $(e, a)$. The proof follows from the lemma and the estimate

$$\|g(x) - a\| \leq \|g(x) - g(a)\| + \|g(a) - a\|.$$

The condition of continuity in the definition of a representation can be further weakened.

5.5 Lemma. Let $\pi : G \to \text{GL}(E)$ be a homomorphism with the following properties:

1) all $\pi(g)$ are bounded.
2) There is a neighborhood of the identity whose image in $B(E)$ is bounded.
3) There is a dense subset of vectors $a \in E$ such that $g \mapsto \pi(g)(a)$ is continuous.

Then $\pi$ is a continuous representation.

Proof. We have to show that for fixed $a$ the function $x \mapsto \pi(x)a$ is continuous. It is obviously enough to proof this at the unit element $x = e$. Hence we have to estimate $\|\pi(x)a - a\|$. For some $b$ in the dense subset we use the estimate

$$\|\pi(x)a - a\| \leq \|\pi(x)a - \pi(x)b\| + \|\pi(x)b - b\| \|b - a\|.$$

If we choose $b$ close enough to $a$ we obtain the desired result.
§5. Generalities about representations

Algebraic Irreducibility
Let \( \pi : G \rightarrow \text{GL}(V) \) be a representation. A subspace \( W \subset V \) is called invariant if \( g \in G \) and \( a \in W \) implies \( ga \in W \). Then we obtain a representation \( \pi' : G \rightarrow \text{GL}(W) \). A representation \( \pi : G \rightarrow \text{GL}(V) \) is called \emph{algebraically irreducible} if \( V \neq 0 \) and if besides \( \{0\} \) and \( V \) there are no invariant subspaces. Let \( W_1, W_2 \) be two invariant subspaces of \( V \). Then \( W_1 + W_2 \) and \( W_1 \cap W_2 \) are also invariant. If \( W_1 \) and \( W_2 \) are irreducible then either they are equal or their intersection is zero.

Topological Irreducibility
Let now \( \pi : G \rightarrow \text{GL}(V) \) be a continuous representation. It is called \emph{topologically irreducible} if there is no closed invariant subspace different from \( \{0\} \) and \( V \).

For finite dimensional representations (this means that \( V \) is finite dimensional) algebraic and topological irreducibility is the same.

A representation of a topological group on a Hilbert space \( H \) is called \emph{unitary} if it is continuous and if all operators \( \pi(g) \) are unitary operators. This means concretely
\[
\langle ga, gb \rangle = \langle a, b \rangle
\]
for \( a, b \in H \) and \( g \in G \). It is enough to demand this for \( a = b \). If we talk about an irreducible unitary representation, we always mean that it is topologically irreducible.

We describe a fundamental example of a unitary representation. Let \( G \) be a locally compact group. We consider a closed subgroup \( H \subset G \). For sake of simplicity we assume that both are unimodular. Then \( dx \) is left- and right invariant. We consider the space of right cosets \( H \backslash G \). The group \( G \) acts on \( H \backslash G \) by multiplication from the right. This is an action from the right. Let \( f : H \backslash G \rightarrow \mathbb{C} \) be a function and \( g \in G \). We define the translate \( R_g f \) of \( f \) by \( (R_g f)(x) = f(xg) \). This is an action from the left of \( G \) on the set of function on \( H \backslash G \). This defines a map
\[
R : G \rightarrow \text{GL}(L^2(H \backslash G, dx)).
\]
By means of Theorem 5.3 one can show that this representation is continuous. It is obviously a unitary representation. In the special case \( H = \{e\} \) one obtains the so-called regular representation of \( G \) on \( L^2(G) \).

One of the basic problems of harmonic analysis is the investigation of this representation and to describe its spectral decomposition. This problem has been studied for the regular representation of semi simple groups \( G \) (for example \( \text{SL}(n, \mathbb{R}) \)) by Harish Chandra. In the theory of automorphic forms one studies the case where \( H = \Gamma \) is a discrete subgroup such that \( \Gamma \backslash G \) has finite volume.

What means “spectral decomposition”? This is not so easy to explain and not the goal of these notes. Nevertheless it is useful to get an idea of it. We
give two examples. The first example is the group $S^1$ of complex numbers of absolute value one (circle group). The functions $f$ on $S^1$ correspond to the periodic functions (period $2\pi$) $F$ on $\mathbb{R}$ through

$$F(t) = f(\exp(2\pi i t)).$$

From the theory of Fourier series one knows that $L^2(S^1)$ is the direct Hilbert sum of the one dimensional subspaces $H(n)$ spanned by $f(\zeta) = \zeta^n$ ($n \in \mathbb{Z}$). These are invariant subspaces. The spectral decomposition of the regular representation of $S^1$ is

$$L^2(S^1) = \bigoplus_{n \in \mathbb{Z}} H(n).$$

The second example deals with the regular representation of $\mathbb{R}$. There are also one dimensional spaces $H(t)$ generated by the function $x \mapsto e^{2\pi i tx}$ which are invariant under translations $t \mapsto t + a$. Now $t$ can be an arbitrary real number. But the difference is that now $H(t)$ is not contained in $L^2(\mathbb{R})$. Nevertheless the theory of Fourier transformation shows that all $f$ in a certain dense subspace of $L^2(\mathbb{R})$ can be written in a unique way in the form

$$f(t) = \int_{-\infty}^{\infty} g(u) e^{2\pi i u t} du.$$

Hence one is tempted to say that $L^2(\mathbb{R})$ is the direct integral of the spaces $H(t)$ and to write this in the form

$$L^2(\mathbb{R}) = \int_{\mathbb{R}} H(t) dt.$$

For general $G$ the spectral decomposition will include both types (discrete and continuous spectra) and the constituents will not be one-dimensional but irreducible unitary representations (often infinite dimensional).

**Intertwining Operators**

A morphism between two continuous representations $\pi_i : G \to \text{GL}(E_i)$ on Banach spaces is a continuous linear map $E_1 \to E_2$ which is compatible with the action of $G$ in an obvious sense. Such morphisms are also called “intertwining operators”. It is clear what it means that an intertwining operator is an isomorphism. If $F \subset E$ is a closed $G$-invariant subspace then the natural inclusion $F \hookrightarrow E$ is a morphism. We call $(G, F)$ a sub-representation of $(G, E)$.

For unitary representations we will make use of a more restrictive notion of isomorphy. An isomorphism $H_1 \to H_2$ between two unitary representations $\pi : G \to \text{GL}(H_i)$ is called a unitary isomorphism, or an isomorphism of unitary representations, if the isomorphism $H_1 \to H_2$ is an isomorphism of Hilbert spaces. This means that it preserves the scalar products.
6. The convolution algebra

Let $G$ be a locally compact group with a chosen Haar measure. The convolution of two functions $f, g \in \mathcal{C}_c(G)$ is defined by

$$(f * g)(x) = \int_G f(y)g(y^{-1}x)dy.$$ 

The convolution defines an associative product on $\mathcal{C}_c(G)$. We leave the proof of the associativity as an exercise. Hence $\mathcal{C}_c(G)$ has the structure of an associative $\mathbb{C}$-algebra.

Let $\pi : G \to \text{GL}(H)$ be a continuous representation on a Banach space. For any $f \in \mathcal{C}_c(G)$ and any $h \in H$ we can consider the function

$$G \to H, \quad x \mapsto f(x)\pi(x)h.$$ 

It is continuous and with compact support. Hence we can define the integral

$$\int_G f(x)\pi(x)hdx.$$ 

If we vary $h$ we get an operator $H \to H$. One can check that it is linear and continuous.

We denote this operator by

$$\pi(f) = \int_G f(x)\pi(x)dx.$$ 

One verifies

$$\pi(f_1 * f_2) = \pi(f_1) \circ \pi(f_2).$$ 

What we obtain is an algebra homomorphism

$$\pi : \mathcal{C}_c(G) \to \text{End}(H).$$ 

The image of $\pi$ consists of continuous linear operators $T : H \to H$.

Now we assume that $H$ is a Hilbert space. We denote the adjoint of an operator $T \in \text{End}(H)$ by $T^*$. It is defined by the formula $\langle Tx, y \rangle = \langle x, T^*y \rangle$. The existence of $T^*$ follows from the Riesz lemma. Of course $T^*$ is continuous as $T$, and moreover both have the same norm.

We define

$$f^*(x) := \Delta(x^{-1})f(x^{-1}).$$ 

We now assume that $\pi$ is unitary. It is easy to check in this case that the new map $\pi$ has the property that

$$\pi(f^*) = \pi(f)^*.$$
What we obtained is a $\ast$-algebra representation. We describe briefly what this means. An algebra $A$ is a vector space (in our case over $\mathbb{C}$) together with a bilinear map

$$A \times A \rightarrow A, \quad (a, b) \mapsto ab.$$ 

We assume that this is associative but we do not assume that $A$ contains a unit element. An involution on $A$ is a map

$$A \rightarrow A, \quad a \mapsto a^*,$$

with the properties

a) $(a + b)^* = a^* + b^*$, \quad $(Ca)^* = \bar{C}a^*$,

b) $(ab)^* = b^*a^*$.

c) $a^{**} = a$.

6.1 Definition. A $\ast$-algebra $(A, \ast)$ is an associative algebra (not necessarily with unit) together with a distinguished involution $\ast$.

An example of a $\ast$-algebra is the convolution algebra $\mathcal{C}_c(G)$ with the involution defined above. Another example of a $\ast$-algebra is the space $\text{End}(H)$ of continuous linear operators on a Hilbert space $H$. Multiplication is the composition of operators and the $\ast$-operator is given by the adjoint.

By a representation of an algebra $A$ on a vector space $V$ one understands a linear map $A \rightarrow \text{End}(V)$ which is compatible with multiplication. By a $\ast$-algebra representation of a $\ast$-algebra $A$ on a Hilbert space $H$ we understand a representation

$$A \rightarrow \text{End}(H)$$

such the image of $A$ consists of continuous operators and that is also compatible with the star operators. We have seen that a unitary representation $\pi : G \rightarrow \text{GL}(H)$ induces a $\ast$-algebra representation $\pi : \mathcal{C}_c(G) \rightarrow \text{End}(H)$.

There are obvious notions of irreducibility:

A representation $A \rightarrow \text{End}(V)$ of an algebra is called algebraically irreducible if the image of $A$ is not zero and if there is no invariant subspace of $V$ different from $0$ and $V$.

A $\ast$-algebra representation $A \rightarrow \text{End}(H)$ is called topologically irreducible if the image if $A$ is non zero and if there is no closed invariant subspace of $H$ different from $0$ and $H$.

An example of a finite dimensional algebra representation is the tautological representation of $A = \text{End}(V)$ on $V$. It is just the identity map $\text{End}(V) \rightarrow \text{End}(V)$. At least in the finite dimensional case it is clear that this representation is irreducible. A special case of a fundamental structure theorem of Wedderburn states (in the case of the ground field $\mathbb{C}$):
6.2 Theorem. Let $\pi : A \to \text{End}(V)$ be an irreducible representation of an algebra $A$ on a finite dimensional vector space $V$. Then $\pi$ is surjective. We don’t give the proof here and refer to the text book of S. Lang on algebra. To be honest, we mention that Lang treats only the case where $A$ contains a unit element. The general case can be reduced by the technique of adjoining a unit element.

A trivial consequence of Theorem 6.2 is as follows. Let $T : V \to V$ be a linear operator that commutes with all $\pi(a)$, $a \in A$. Then $T$ is a multiple of the identity. A basic result states that this carries over to the infinite dimensional case.

6.3 Theorem (Schur’s lemma for algebra representations). Let $\pi$ be a topologically irreducible unitary representation of a $*$-algebra $A$ on a Hilbert space $H$. Assume that $T : H \to H$ is a linear and continuous operator that commutes with all $A = \pi(a)$, $a \in A$. Then $T$ is a constant multiple of the identity.

Corollary. If $A$ is abelian then $H$ is one-dimensional.

Proof. We will not give the proof in the infinite dimensional case The proof rests on the spectral theorem for self adjoint operators. This is explained in the Appendices, Sect.1 and 2. One has to use Lemma VI.2.10. We give the details. First one can assume that $T$ is self adjoint, since one can use the decomposition $2T = (T + T^*) - i(i(T - T^*))$. So we can assume that $T$ is self adjoint and commutes with all $A = \pi(a)$. We assume that $T$ is not a multiple of the identity. Then, by Lemma VI.2.10, there exists a $B$ in the bi-commutant (see VI.2) of $T$ whose kernel is different from 0 and $H$. Since $B$ commutes with all $A = \pi(a)$, its kernel is invariant under all $A$. This contradicts the irreducibility.

The same theorem is true for irreducible unitary representations of locally compact groups. Actually it is a consequence of Theorem 6.3 as we shall point out. The argument would be very easy if there exists for $g \in G$ a Dirac function $\delta_g \in \mathcal{C}_c(G)$ which means

$$\delta_g(x) = 0 \text{ for } x \neq g \quad \text{and} \quad \int_G \delta_g(x)dx = 1.$$ 

Such a situation is of course rare, but it occurs, namely for finite groups. A simple computation then gives $\pi(\delta_g) = \pi(g)$. From this one can deduce that a subspace of $H$ is invariant under all $\pi(g)$, $g \in G$, if and only if it is invariant under all $\pi(f)$, $f \in \mathcal{C}_c(G)$. Actually there is a weak variant of Dirac functions.

6.4 Lemma. For each locally compact group $G$ there exists a sequence of functions $\delta_n \in \mathcal{C}_c(G)$ with the following properties.

1) $\text{supp}(\delta_{n+1}) \subset \text{supp}(\delta_n)$. 

[\text{DirSeq}]
2) For each neighborhood $U$ of the identity there exists an $n$ such that $\text{supp}(\delta_n) \subset U$.

3) $\delta_n(x^{-1}) = \delta_n(x)$.

4) $\delta_n(x) \geq 0$ and $\int_G \delta_n(x)dx = 1$.

We call $(\delta_n)$ a Dirac sequence.

**6.5 Lemma.** Let $(\delta_n)$ be a Dirac sequence. Then $\pi(\delta_n)$ converges to the identity in the sense

$$\lim_{n \to \infty} \|\pi(\delta_n)h - h\| = 0.$$  
(This means pointwise convergence.)

**Proof.** We have

$$\|\pi(\delta_n)h - h\| \leq \int_G \delta_n(x)\|\pi(x)h - h\|.$$

Let $\varepsilon > 0$. For $n$ big enough we have $\|\pi(x)h - h\| < \varepsilon$ for all $x \in U_n$. We obtain $\|\pi(\delta_n)h - h\| < \varepsilon$.

There is an obvious generalization. Let $g \in G$ then from Lemma 6.5 we see that $\pi(f_n) \circ \pi(g) \to \pi(g)$ (pointwise) A simple calculation shows

$$\pi(f) \circ \pi(g) = \pi(\tilde{f}) \quad \text{where} \quad \tilde{f}(x) = \Delta(g)f(xg^{-1}).$$

This shows the following result.

**6.6 Lemma.** Let $G \to \text{GL}(H)$ be a unitary representation and let $W \subset H$ be a closed subspace. Assume that there exists a subalgebra $A \subset C_c(G)$ that contains a Dirac sequence and that is invariant under translation $f(x) \mapsto f(xg)$ for all $g \in G$ and such that $W$ is invariant under $A$. Then $W$ is invariant under $G$.

As an application of Lemma 6.6 we get the following lemma.

**6.7 Lemma.** Let $\pi : G \to \text{GL}(H)$ be a unitary representation. A closed subspace $W \subset H$ is invariant under $G$ if and only if it is invariant under $C_c(G)$.

Schur’s lemma now can be formulated also for group representations.

**6.8 Theorem (Schur’s lemma for group representations).** Let $\pi : G \to \text{GL}(H)$ be an irreducible unitary representation of a locally compact group. Every linear and continuous operator $T : H \to H$ which commutes with all $\pi(g), g \in G$, is a multiple of the identity.

**Corollary.** If $G$ is abelian then then $H$ is one-dimensional.
6.9 Lemma. Let \( \pi : G \rightarrow \text{GL}(H) \) be a unitary representations and \( A, B \) be two invariant closed subspaces. Assume the the restriction of \( \pi \) to \( A \) is (topologically) irreducible. Then either \( A \) is orthogonal to \( B \) or the representation \( \pi|A \) occurs in \( \pi|B \).

**Corollary.** If both \( A \) and \( B \) are irreducible then either they are orthogonal or isomorphic (as \( G \)-representations).

**Proof.** We consider the pairing \( \langle \cdot, \cdot \rangle : A \times B \rightarrow \mathbb{C} \). We first notice that it is non degenerate in the following sense. For each \( a \in A \) their exists a \( b \in B \) such that \( \langle a, b \rangle \neq 0 \) and conversely. This is clear since the orthogonal complement of \( B \) intersected with \( A \) is a closed invariant subspace. Next we construct a linear map \( f : A \rightarrow B \). By the Lemma of Riesz there exists for each \( a \in A \) a unique \( f(a) \) in \( B \) such that \( \langle a, b \rangle = \langle f(a), b \rangle \) for all \( b \in B \). One easily checks that this is an intertwining operator. \( \square \)

6.10 Definition. A unitary representation \( \pi : G \rightarrow \text{GL}(H) \) is called **completely reducible** if \( H \) can be written as the direct Hilbert sum of pairwise orthogonal closed invariant subspaces

\[
H = \bigoplus_i H_i
\]

which are irreducible as \( G \)-representations.

In general we denote by \( \hat{G} \) the set of all isomorphy classes of irreducible unitary representations of \( G \) and call it the **unitary dual** of \( G \). Recall that each irreducible unitary representation \( \pi : G \rightarrow \text{GL}(H) \) is one dimensional if \( G \) is abelian. Hence it is of the form \( \pi(g)(h) = \chi(g)h \) where \( \chi \) is a character of \( G \).

By definition, this is a continuous homomorphism from \( G \) into the group of complex numbers of absolute value 1. Unitary isomorphic representations give the same character. This gives a bijection with \( \hat{G} \) and the set of all unitary characters. Characters can be multiplied in an obvious way. Hence, for abelian \( G \), the set \( \hat{G} \) is a group as well. One can show that it carries a structure as locally compact group.

6.11 Proposition. Let \( \pi : G \rightarrow \text{GL}(H) \) a unitary representation which is completely reducible,

\[
H = \bigoplus_{i \in I} H_i, \quad H_i \subset H.
\]

Let \( \tau \in \hat{G} \). Then

\[
H(\tau) = \bigoplus_{i \in I, \pi_i \in \tau} H_i
\]

is the closure of the sum of all irreducible closed invariant subspaces of \( H \) that are of type \( \tau \). In particular, it is independent of the choice of the decomposition.
This follows immediately from Lemma 6.9.

We call $H(\tau)$ the $\tau$-isotypic component of $\pi$. This is well-defined. The irreducible components $H_i$ are usually not well-defined. Look at the example of the group $G$ that consists only of the unit element. Nevertheless the so-called multiplicity

$$m(\tau) := \#\{i \in I; \pi_i \in \tau\} \leq \infty$$

is independent on the choice of the decomposition. This can be seen as follows. Let $(H(\tau), \tau)$ be a realization of $\tau$. We consider the vector space of all intertwining operators $H \to H(\tau)$. The space of intertwining operators $H_i \to H(\tau)$ is zero if $\pi_i$ is not in $\tau$ and – by Schur’s lemma – one dimensional otherwise. From this follows easily the space of intertwining operators $H \to H(\tau)$ has dimension $m(\tau)$. This shows the invariance of $m(\tau)$.

This gives us the following result.

6.12 Proposition. Let $\pi : G \to \text{GL}(H)$ be a completely reducible unitary representations. The multiplicities

$$m(\tau) := \#\{i \in I; \pi_i \in \tau\} \leq \infty$$

(in the notation of Proposition 6.11 are well-defined). Two completely reducible representations are unitary isomorphic if and only of their multiplicities agree.

7. Generalities about compact groups

In this section we treat some general facts about representations of compact groups. Readers who are mainly interested in the classification of the irreducible unitary representations of the group $\text{SL}(2, \mathbb{R})$ can skip this section, since the only compact group which occurs in this context is the group $\text{SO}(2, \mathbb{R})$. This group is not only compact but also abelian which makes the theory rather trivial.

We need some results of functional analysis. We recall the notion of equicontinuity:

7.1 Definition. A set $\mathcal{M}$ of functions on a topological space $X$ is called equicontinuous at a point $a \in X$ if for any point $\varepsilon > 0$ their exists a neighborhood $U$ of $a$ such that

$$|f(x) - f(a)| < \varepsilon \quad \text{for all } x \in U, \ f \in \mathcal{M}.$$  

The set is called equicontinuous if this is the case at all $a \in X$.

(The point is the independence of the neighborhood $U$ from $f$.) We recall a basic result from functional analysis.
7.2 Theorem (theorem of Arzela-Ascoli). Let $X$ be a locally compact space with countable basis of the topology. Let $M$ be an equicontinuous set of functions on $X$ such that the set of numbers $f(x)$, $f \in M$, is bounded for every $x \in X$. Then each sequence of $M$ admits a subsequence that converges locally uniformly on $X$.

There are variants of this theorem in which equicontinuity does not appear. Let for example $X \subset \mathbb{R}^n$ be an open subset and assume that $M$ is a set of differentiable functions such that there exists a constant $C$ such that

$$|f(x)| \leq C \quad \text{and} \quad |(\partial f/\partial x)(x)| \leq C \quad \text{for all } x \in X.$$ 

Then the mean value theorem of calculus shows that this set is equicontinuous.

Another main tool will be the spectral theorem for compact operators on Hilbert spaces. Let $H$ be a Hilbert space. A linear and continuous operator $T : H \rightarrow H$ is called compact if the image any bounded set is contained in a compact set. For example this is the case if the image of $T$ is finite dimensional. The identity is compact if and only if $H$ is finite dimensional. The set of all compact operators is closed under the operator norm. So, let $T_1, T_2, \ldots$ be a sequence of compact operator and $T$ another bounded operator such that $\|T_n - T\|$ tends to 0. Then $T$ is compact. We will not give a proof here.

Recall that an operator $T$ is called normal if it commutes with its adjoint, $T \circ T^* = T^* \circ T$.

7.3 Theorem (Spectral theorem for compact operators). Let $T : H \rightarrow H$ be a compact and normal operator. The set of eigenvalues is either finite or it is countable and 0 is the only accumulation point of it. The eigenspaces $H(T, \lambda)$ are pairwise orthogonal and for $\lambda \neq 0$ they are finite dimensional. The sum of all eigenspaces is dense in $H$. Hence we have a Hilbert space decomposition

$$H = \bigoplus_\lambda H(T, \lambda).$$

A proof can be found in the Appendices.

We give an example of a compact operator.

7.4 Proposition. Let $X$ be a compact topological space and $dx$ a Radon measure. Let $K \in C(X, X)$ be a continuous function. The operator

$$L_K : L^2(X, dx) \rightarrow L^2(X, dx), \quad L_K(f)(x) := \int_X K(x, y)f(y)dy.$$ 

is a compact (continuous and linear) operator.
We mention that every square integrable function $f$ on a compact space is integrable (since one can write $f = 1 \cdot f$ as product of two square integrable functions). Since $K(x, y)$ for fixed $x$ is an $L^2$-function the existence of the integral in Proposition 7.4 is clear. Clearly the functions $L_K f$ are continuous. Even more we have

$$|L_X(f)(x)| \leq c\|f\|_2$$

with some constant $c$ by the Cauchy-Schwarz inequality. This also implies that $L_X f \in L^2(X, dx)$ and moreover

$$\|L_K f\|_2 \leq C\|f\|_2$$

with some constant $C$. Hence the operator is linear and also continuous.

But we have a stronger property. It is easy to show that the set of functions

$$\{ L_K f; \ f \in L^2(X, dx), \ \|f\|_2 \leq 1 \}$$

is equicondition. This implies that $L_K$ is a compact operator. For this we have to prove the following. Let $f_n \in L^2(X, dx)$ be a sequence of functions such that $\|f_n\|_2 \leq 1$. We have to show that $L_K f_n$ has a sub-sequence that converges in $L^2(X, dx)$. The theorem of Arzela-Ascoli shows that $L_K f_n$ converges uniformly. Hence it converges point-wise and all functions are bounded by a joint constant. Since $X$ is compact, constant functions are integrable and we can apply the Lebesgue limit theorem to obtain convergence in $L^2(X, dx)$. □

7.5 Proposition. Let $\pi : G \to GL(H)$ be a unitary representation of a locally compact group $G$ on a Hilbert space $G$. Assume that there exists a Dirac sequence $\delta_n \in C_c(G)$ such that all $\pi(\delta_n)$ are compact operators. Then the representation decomposes into irreducibles with finite multiplicities.

Proof. We consider pairs that consist of a closed invariant subspace $H' \subset H$ such the restriction of $\pi$ to $H'$ is completely reducible and a distinguished decomposition $H' = \bigoplus_{i \in I} H'_i$ into irreducibles. We define an ordering for such pairs. The pair $H' = \bigoplus_{i \in I} H'_i$ is less or equal than the pair $H'' = \bigoplus_{j \in J} H''_j$ if each space $H'_i$ equals some $H''_j$. (Especially $H' \subset H''$). From Zorn’s lemma easily follows that there exists a maximal member. We call its orthogonal complement $U$. This space cannot contain any irreducible subspace since this could be used to enlarge the maximal element. Hence we have to show:

let $\pi$ be a representation as in the proposition which is not zero. Then there exists at least one irreducible closed subspace.

To prove this we choose an element $f$ of the Dirac sequence such that $\pi(f)$ is not identically zero. This element will kept fixed during the proof. We also choose an eigenvalue $\lambda \neq 0$ of $\pi(f)$ Let $H(f, \lambda) \subset H$ the eigenspace. This is a finite dimensional vector space.
There may be other invariant closed subspaces which have a non-zero intersection with $H(f, \lambda)$. We choose a closed subspace $E$ such that the dimension of its intersection with $H(f, \lambda)$ is non-zero and minimal. Then we set $W = E \cap H(f, \lambda)$. There still may exist several closed invariant subspaces $H$ that share with $E$ the property $W = F \cap H(f, \lambda)$. We take the intersection of all these $F$ and get in this way a smallest closed invariant subspace $F \subset E$ with $W = F \cap H(f, \lambda)$. We claim that this $F$ is irreducible. For this we take any orthogonal decomposition $F = A \oplus B$. The eigenvalue $\lambda$ must occur as eigenvalue of $\pi(f)$ in one of the spaces $A, B$. (The restriction of a compact operator to a closed invariant subspace remains compact and hence decomposes into eigen spaces.) Let us assume that it occurs in $A$. Then $A \cap H(f, \lambda)$ is not zero. It must agree with $W$ because of the minimality property of $\dim W$. Moreover it must agree with $F$ because of the minimality property of $F$. This shows the irreducibility.

It remains to prove that the multiplicities are finite. Let $\tau \in \hat{G}$. Let $H_1, \ldots, H_m$ be pairwise orthogonal invariant closed subspaces of type $\tau$. We claim that $m$ is bounded. There exists an element $f = \delta_n$ from the Dirac sequence such that $\pi(f)$ is not zero on $H_1$. There exists a non-zero eigenvalue $\lambda$. This eigenvalue then occurs in all $H_i$ since they are all isomorphic (as representations). Since the multiplicity of the eigenvalue is finite the number $m$ must be bounded.

A special case of Proposition 7.5 gives the following basic result.

7.6 Theorem. Let $K$ be a compact group. The regular representation of $K$ on $L^2(K)$ (translation from the right) is completely reducible with finite multiplicities.

Proof. Let $f \in C(K)$. We have to show that the operator $R_f$ is compact. Recall that $R_f$ is defined as Bochner integral

$$R_f(h) = \int_K f(x) R_x(h) dx, \quad (R_x h)(y) = h(yx).$$

It looks natural to get this as function by interchanging the evaluation if this function with integration, i.e. one should expect

$$R_f(h)(y) = \int_K f(x) h(yx) dx.$$

This is actually true but one has to be careful with the argument since the evaluation map $h \mapsto h(y)$ is not a continuous linear functional on the Hilbert space $L^2(K)$. Instead of this one uses the following argument. Two elements of a Hilbert space are equal if and only if their scalar products with an arbitrary vector are equal. Taking scalar product with a vector is a continuous linear
functional which can be exchanged with the Bochner integral. In this way one obtains the desired formula. We can rewrite the formula as

$$R_f(h)(x) = \int_{K} f(x^{-1}y)h(y)dy.$$

This is the integral operator with kernel $K(x, y) = f(x^{-1}y)$. $\square$

There is a more general result.

7.7 Proposition. Every unitary representation of a compact group $K$ on a Hilbert space $H$ is completely reducible.

Proof. We have to show that the operators

$$T = \pi(f) = \int_{K} f(x)\pi(x)dx$$

are compact. For this it is sufficient to construct for each $\varepsilon > 0$ an operator $T'$ with finite range such that $\|T - T'\| < \varepsilon$.

7.8 Theorem. Every topologically irreducible representation of a compact group on a Hilbert space is finite dimensional.

7.9 Proposition. Let $\pi : K \to \text{GL}(H)$ be a Banach representation of a compact group on a Hilbert space $H$. There exists a Hermitian product on $H$ whose norm is equivalent to the original one and such that $\pi$ is unitary.

The proof is easy. One replaces the original Hermitian product $\langle \cdot, \cdot \rangle$ by the new scalar product

$$\int_{K} \langle \pi(k)(x), \pi(k)(y) \rangle.$$

(This is called Weyl’s unitary trick.) $\square$

There is a broad structure theory for representations of compact groups, in particular of compact Lie groups. We need only little of it. Basic for this theory is the notion of the character of a finite dimensional representation $\pi : G \to \text{GL}(H)$. It is the following function on $G$:

$$\chi_{\pi} : G \to \mathbb{C}, \quad \chi_{\pi}(x) = \text{tr}(\pi(x)).$$

For a one-dimensional representation this is the usual the underlying character. The character is a class function. This means

$$\chi(gyy^{-1}) = \chi(x).$$

7.10 Peter-Weyl theorem. Let $\pi : K \to \text{GL}(H)$ be an unitary representation of a compact group and let $\sigma$ be an irreducible unitary representation of $K$. We denote by $H(\sigma)$ the $\sigma$-isotypic component of $H$. We denote by $P : H \to H(\sigma)$ the projection operator. Then

$$P = \dim(\sigma)\int_{K} \overline{\chi(k)}\pi(k).$$
Proof. A proof can be found in the appendices.

Theorem 7.6 admits the following generalization:

**7.11 Theorem.** Let $G$ be a unimodular locally compact group and $\Gamma \subset G$ a discrete subgroup such that $\Gamma \backslash G$ is compact. Then the representation of $G$ on $L^2(\Gamma \backslash G)$ (translation from the right) is completely irreducible with finite multiplicities.

Proof. As in the proof of Theorem 7.6 we can rewrite the operator $R_f$ as an integral operator

$$\int_G f(y)h(xy)dy = \int_G f(x^{-1}y)h(y)dy = \int_{\Gamma \backslash G} \sum_{\gamma \in \Gamma} f(x^{-1}\gamma y)dy.$$ 

This is an integral operator with kernel

$$K(x, y) = \sum_{\gamma \in \Gamma} f(x^{-1}\gamma y).$$

Since $f$ has compact support, this sum is locally finite and $K$ is a continuous function on $X \times X$ where $X$ is the compact space $\Gamma \backslash G$. So we can apply Proposition 7.4.

This theorem is of great importance for the theory of automorphic forms and is one reason to study the irreducible representations of $G$. 

\[\square\]
Chapter II. The real special linear group of degree two

1. The simplest compact group

We study the group
\[ K = \text{SO}(2, \mathbb{R}). \]
So \( K \) consists of all real \( 2 \times 2 \) matrices \( k \) of determinant 1 with the property
\[ k'k = e. \]
Because of
\[ k^{-1} = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}, \quad \left( k = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right) \]
this means that \( k \) is of the form
\[ k = \begin{pmatrix} a & -b \\ b & a \end{pmatrix}, \quad a^2 + b^2 = 1. \]
For \( k \in K \) the complex number \( \zeta = a + ib \) is of absolute value 1. Recall that the set of all complex numbers of absolute value 1 is a group under multiplication. One easily checks that the map
\[ \text{SO}(2, \mathbb{R}) \rightarrow S^1, \quad k \mapsto \zeta, \]
is an isomorphism of locally compact groups. So we see that \( K \) is a compact and abelian group. Hence we know that each irreducible unitary representation is one-dimensional and corresponds to a character. The characters of \( S^1 \) are easy. They correspond to the integers \( \mathbb{Z} \). For each integer \( n \) we can define
\[ \chi_n(k) = \chi_n(\zeta) := \zeta^n. \]
For an arbitrary unitary representation \( \pi : K \rightarrow \text{GL}(H) \) we can consider the corresponding isotypic component
\[ H(n) := \{ h \in H; \quad \pi(g)(h) = \chi_n(g)h \}. \]
Another way to write the elements of \( \text{SL}(2, \mathbb{R}) \) is
\[ \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}. \]
Here \( \theta \) is determined mod \( 2\pi \mathbb{Z} \). The character \( \chi_n \) in this presentation is given by
\[ \chi_n(k) = e^{2\pi in\theta}. \]
2. The Haar measure of the real special linear group of degree two

We use the following notations:

\[ G = \text{SL}(2, \mathbb{R}) \]
\[ A = \left\{ a_t = \begin{pmatrix} e^t & 0 \\ 0 & e^{-t} \end{pmatrix} ; \ t \in \mathbb{R} \right\} \]
\[ N = \left\{ n_x = \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} ; \ x \in \mathbb{R} \right\} \]
\[ K = \left\{ k_\theta = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} ; \ \theta \in \mathbb{R} \right\} \]

2.1 Lemma (Iwasawa decomposition). The map

\[ A \times N \times K \rightarrow G, \ (a, n, k) \mapsto ank, \]

is topological.

Proof. The elements of \( K \) act as rotations on \( \mathbb{R}^2 \). To any \( g \in G \) one can find a rotation \( k \) such that \( gk \) fixes the \( x \)-axis. Then \( gk \) is triangular matrix. This gives the prove of the lemma. \( \square \)

One can write the decomposition explicitly:

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \left( \frac{1}{\sqrt{c^2 + d^2}} \right) \begin{pmatrix} 1 & ac + bd \\ 0 & 1 \end{pmatrix} \left( \frac{1}{\sqrt{c^2 + d^2}} \right) \begin{pmatrix} d & -c \\ c & d \end{pmatrix}.
\]

We denote the Haar measures on \( A, N, K \) by \( da, dn, dk \). Since \( t \mapsto a_t \) is an isomorphism of groups, we have \( da = dt \) where \( dt \) denotes the standard measure of \( \mathbb{R} \). The measure \( dk \) is normalized such that the volume of \( K \) is 1.

We first consider the group \( P = AN \) of upper triangular matrices in \( \text{SL}(2, \mathbb{R}) \) with positive diagonal. The map \( A \times N \rightarrow P \) is topological (but not a group isomorphism). Recall that

\[
\int_P f(p)dp := \int_A \int_N f(an)dana
\]

is a Haar measure (Lemma I.4.2).

2.2 Proposition. A Haar measure on \( G = \text{SL}(2, \mathbb{R}) \) can be obtained as follows

\[
\int_G f(x)dx = \int_A \int_N \int_K f(ank)dkdn da.
\]

Proof. Since \( K \) is compact we have \( \Delta_G | K = \Delta_K \). Hence the invariant quotient measure on \( K \backslash G \) exists. There is a natural topological map \( P \rightarrow K \backslash G \). The quotient measure gives a Haar measure on \( P \). The rest comes from defining properties of a quotient measure (Proposition I.4.3). \( \square \)
3. The principal series

We construct the basic unitary representations of $G = \text{SL}(2, \mathbb{R})$.

The principal series

We take $G = \text{SL}(2, \mathbb{R})$, $K = \text{SO}(2, \mathbb{R})$. We also consider the group $P$ of upper triangular matrices

$$p = \begin{pmatrix} a & * \\ 0 & a^{-1} \end{pmatrix}$$

with positive diagonal elements. The Iwasawa decomposition gives a natural bijection

$$P \setminus G \to K, \quad pk \mapsto k.$$

Since $G$ acts on $P \setminus G$ from the right, we get an action of $G$ on $K$. This can be described as follows.

Let $k \in K$, $g \in G$. We write the Iwasawa decomposition of $kg$ in the form

$$kg = \beta_g(k)\alpha_g(k), \quad \alpha_g(k) \in P, \quad \beta_g(k) \in K.$$ 

The the action of $G$ on $K$ is given by

$$K \times G \to K, \quad (k, g) \mapsto \alpha_g(k).$$

Let $dk$ be a Haar measure of $K$. It is not invariant under the action of $G$. Instead of this the following transformation formula holds. Recall that $\Delta(p) = a^2$ is the modular function of $P$.

3.1 Lemma. Let $g \in G$. We consider the (continuous) maps $\alpha_g : K \to K$ and $\beta_g : K \to P$ which are defined by $kg = \beta_g(k)\alpha_g(k)$. Then for each $f \in C_c(K)$ the formula

$$\int_K f(\alpha_g(k))\Delta(\beta_g(k))dk = \int_K f(k)dk$$

holds.

Proof. Since $G$ and $K$ are unimodular we can consider on $G/K$ the invariant quotient measure and this is a Haar measure on $P$ which we can identify with $G/K$. We choose an arbitrary function $\varphi \in C_c(P)$ with the property

$$\int_P \varphi(p)dp = 1.$$ 

Then we consider the function $F(pk) = \varphi(p)f(k)$. This is a function in $C_c(G)$. The defining formula for the quotient measure on $K \setminus G$ is

$$\int_G F(x)dx = \int_P \int_K F(pk)dkdp = \int_K f(k)dk.$$
We use the right invariance of the Haar measure on $G$ to obtain
\[ \int_K f(k)dk = \int_G F(xy)dx = \int_P \int_K F(p\beta_g(k)\alpha_g(k))dkdp. \]
We first integrate over $p$. Since the factor $\beta_g(k) \in P$ is on the right from $p$ we get
\[ \int_K f(k)dk = \int_P \int_K F(p\alpha_g(k))\Delta(\beta_g(k))dkdp = \int_K f(\alpha_g(k)\Delta(\beta_g(k))dk. \]
We derive a corollary from Lemma 3.1.

3.2 Corollary of Lemma 3.1. Let $f : G \rightarrow \mathbb{C}$ be a function such that $f|K$ is integrable and such that
\[ f(pg) = a^2 f(p) = \Delta(p)f(p) \quad \text{for all } p \in P, g \in G. \]
Then for each $g \in G$ the function
\[ \tilde{f}(x) = f(xy), \quad x \in G, \]
has the same property and we have
\[ \int_K f(x)dx = \int_K \tilde{f}(x)dx. \]

Proof. It is enough to prove this for $f(\alpha_g(k))$ instead of $\tilde{f}$, because the extra factor is a continuous function on the compact space $K$. The proof that we have in mind makes use of the fact that $\alpha = \alpha_g$ is a diffeomorphism $K \rightarrow K$. This can be expressed elementary in the following way. Consider the natural map $\mathbb{R} \rightarrow K$, $\theta \mapsto k_\theta$. Then $\alpha$ can be liftet to a diffeomorphism $\beta : I \rightarrow J$ where $I,J \subset \mathbb{R}$ are intervals of length $2\pi$. The function $f$ lifts to a periodic function $F$ on $\mathbb{R}$. The Haar measure corresponds to $\int_J F(s)ds$. Now the claim follows from the transformation formula
\[ \int_I F(\beta(t))|\dot{\beta}(t)|dt = \int_J F(s)ds. \]
This proves the Corollary.

Now we consider the space of all functions
\[ f(pg) = a^{1+s} f(g) = \Delta(p)^{(1+s)/2}f(g), \quad p \in P, g \in G. \]
Here $s$ can be an arbitrary complex number. The group $G$ acts on the set of these functions by translation from the right. The Iwasawa decomposition
shows that such a function is determined by its restriction to $K$ and every function on $K$ is the restriction of such a function $f$. Hence we defined an action of $G$ (depending on $s$) on functions on $K$. It can be described as follows.

Let $f$ be a function on $K$ and $g \in G$. Then the transformed function is

$$\tilde{f}(k) = \Delta(\beta_g(k))^{(1+s)/2} f(\alpha_g(k)).$$

**Claim.** a) Let $f \in L^2(K, dk)$. Then the same is true for $\tilde{f}$.

b) Let $f$ be a zero function. Then this true also for $\tilde{f}$.

The proof is the same as that of Corollary 3.2.

Now we introduce the space $\mathcal{H}(s)$ of all functions on $G$ with the property

$$f(pg) = a^{1+s} f(g), \quad p \in P, \; g \in G$$

and such that the restriction to $K$ is contained in $L^2(K, dk)$. The above claim shows that $G$ acts on $\mathcal{H}(s)$. The space of zero functions (with respect to the Haar measure) $\mathcal{N}(s)$ is invariant. Hence the group acts on $H(s) = \mathcal{H}(s)/\mathcal{N}(s)$. This space can be identified with $L^2(K, dk)$. We transport the Hermitian product of $L^2(K, dk)$ to $H(s)$. By means of Lemma I.5.5 it is easy to show that this representation is continuous.

### 3.3 Proposition (Principal Series Representations).

**PrinS** For each complex $s$ there is a (continuous) Banach-representation of $G = SL(2, \mathbb{R})$ on the space $L^2(K, dk)$ which can be defined as follows. Take a square integrable function $f$ on $K$ and extend it to a function on $G$ with the property

$$f(px) = a^{1+s} f(x) \quad (x \in G).$$

Consider the translation of $G$ from the right on these functions.

We will see that the these representations play a fundamental role. They are not irreducible. We can consider the subspaces $H^{\text{even}}(s)$ and $H^{\text{odd}}(s)$ of $\mathcal{H}(s)$ and similarly $H^{\text{even}}(s)$, $H^{\text{odd}}(s)$ of $H(s)$ that are defined through $f(-g) = \pm f(g)$.

### 3.4 Remark. **Rpeo** The principal series is the direct sum of the even and the odd principal series

$$H(s) = H^{\text{even}}(s) \oplus H^{\text{odd}}(s)$$

which are defined through $f(-g) = \pm f(g)$.

Even though the principal series act on a Hilbert space ($L^2(K, dk)$) these representations are only Banach representations. But in particular cases they can be used to construct unitary representations. The easiest case is as follows.
3.5 Proposition (Unitary principal series). For \( s \in \mathbb{R} \) the principal series representation is a unitary representation of \( G \). In these cases the decomposition
\[
H(s) = H^{\text{even}}(s) \oplus H^{\text{odd}}(s)
\]
is an orthogonal decomposition.

We will see later that \( H^{\text{even}}(s) \), \( s \in \mathbb{R} \), is always irreducible and that \( H^{\text{odd}}(s) \), \( s \in \mathbb{R} \), is irreducible for \( s \neq 0 \). The odd case \( s = 0 \) is exceptional. Here the representation breaks into an orthogonal sum
\[
H^{\text{odd}}(0) = H^{\text{odd}}(0)^+ \oplus H^{\text{odd}}(0)^- \]
of two representations. Inside \( L^2(K, dk) \) they are generated (as Hilbert spaces) by \( e^{i\theta} \) where \( n > 0 \) resp. \( n < 0 \). Later we will see that these two exceptional unitary representations are irreducible. They are called the Mock discrete series for reasons we will see.

So far we obtained three series of unitary representations which will turn out to be irreducible.

- even principal series \( H^{\text{even}}(s) \) \( (s \in \mathbb{R}) \)
- odd principal series \( H^{\text{odd}}(s) \) \( (s \in \mathbb{R}, s \neq 0) \)
- Mock discrete series \( H^{\text{odd}}(0)^\pm \) \( (2 \text{ representations}) \) derived from the odd principal series in the case \( s = 0 \)

4. The complementary series

We go back to the principal series representation for arbitrary complex \( s \). We can consider the Hermitian pairing
\[
H(s) \times H(-\bar{s}), \quad (f, g) \mapsto \int_K f(x)\overline{g(x)}dx.
\]
This pairing is \( G \)-invariant (use Corollary 3.2).

In what follows it is convenient to introduce the space \( \mathcal{H}^\infty(s) \) of differentiable functions in \( H(s) \). This space is isomorphic to \( \mathcal{C}^\infty(K) \). We want to construct an intertwining operator
\[
M(s) : \mathcal{H}^\infty(s) \xrightarrow{\sim} \mathcal{H}^\infty(-s),
\]
in the sense that it is an isomorphism of vector spaces, compatible with the action of \( G \). Then we can construct a Hermitian pairing
\[
\langle f, g \rangle = \int_G (f(x)M(s)g(x))dx.
\]
(We treated already the case \( s \in \mathbb{R} \) \( (s = -\bar{s}) \). In this case we can take for \( M(s) \) the identity. This lead us to the unitary principal series.)
4.1 Lemma. Let \( f \in \mathcal{H}(s) \) be a differentiable function. Then the integral
\[
\int_N f(wn)dn, \quad w = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},
\]
eexists for \( \text{Re} \ s > 0 \).

Proof. We have to make use of the Iwasawa decomposition
\[
\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{1+x^2}} & 0 \\ \frac{x}{\sqrt{1+x^2}} & \frac{1}{\sqrt{1+x^2}} \end{pmatrix} \begin{pmatrix} \frac{x}{\sqrt{1+x^2}} & \frac{-1}{\sqrt{1+x^2}} \\ \frac{1}{\sqrt{1+x^2}} & \frac{x}{\sqrt{1+x^2}} \end{pmatrix}.
\]
It shows
\[
f(wn) = \frac{1}{\sqrt{1+x^2}^{1+s}} f \left( \begin{pmatrix} \frac{1}{\sqrt{1+x^2}} & \frac{-1}{\sqrt{1+x^2}} \\ \frac{x}{\sqrt{1+x^2}} & \frac{1}{\sqrt{1+x^2}} \end{pmatrix} \right).
\]
Since the function \( f \) is bounded on \( K \), we can compare the integral with
\[
\int_1^\infty \frac{1}{x^{1+s}} dx.
\]
This converges for \( \text{Re} \ s > 0 \). \( \square \)

We can consider the integral in Lemma 4.1 for \( f(xg) \) instead of \( f(x) \).
\[
\int_N f(wng).
\]
This is again a function on \( G \).

4.2 Lemma. Let \( s > 0 \). The operator
\[
(M(s)f)(g) = \int_N f(wn)
\]
defines an isomorphism \( M(s) : \mathcal{H}^\infty(s) \to \mathcal{H}^\infty(-s) \) which is compatible with the action of \( G \).

As we know, \( L^2(K, dk) \) is a Hilbert space. The functions \( e^{in\theta}, n \in \mathbb{Z} \), define an orthonormal basis. This follows for example from the fact that every function in \( \mathcal{C}^\infty(K) \) admits a Fourier expansion
\[
\sum_{n=0}^\infty a_n e^{in\theta}.
\]
Such a Fourier series occurs if and only if \( (a_n) \) is tempered, i.e. rapidly decaying which means that \( a_n P(n) \) is bounded for all polynomials \( P \). The Fourier series and all its derivatives then converge uniformly. Hence they converge also in \( L^2(K) \). We denote by
\[
\varepsilon(s,n) \quad pk \mapsto a^{1+s} e^{in\theta}
\]
the corresponding functions in \( \mathcal{H}(s) \). They build an orthonormal bases. (Recall that we consider at the moment the Hilbert space structure on \( \mathcal{H}(s) \) which is obtained by transportation from \( L^2(K) \)).
4.3 Proposition. Let $\Re s > 0$. Then

$$M(s)\varepsilon(s, n) = c(s, n)\varepsilon(-s, n)$$

where

$$c(s, n) = \frac{2^{1-s}\pi\Gamma(s)}{\Gamma\left(\frac{s+n+1}{2}\right)\Gamma\left(\frac{s+n-1}{2}\right)}.$$ 

An inductive formula for $c(s, n)$ is

$$c(s, 0) = \frac{\Gamma\left(\frac{1}{2}\right)\Gamma\left(\frac{s}{2}\right)}{\Gamma\left(\frac{s+1}{2}\right)}, \quad c(s, \pm 1) = \pm\frac{\Gamma\left(\frac{1}{2}\right)\Gamma\left(\frac{s+1}{2}\right)}{\Gamma\left(\frac{s+2}{2}\right)}.$$ 

The $\Gamma$-function has a meromorphic extension to the whole plane. The poles are in $0, -1, -2, \ldots$. Hence the functions $c(s, n)$ can be holomorphically extended to the complement of $\mathbb{Z}$ in $\mathbb{C}$. We can use this extension to define the intertwining operator $M(s)$ for all $s \notin \mathbb{Z}$.

4.4 Proposition. The intertwining operator $M(s) : \mathcal{H}^\infty(s) \to \mathcal{H}^\infty(-s)$ can be extended from $\Re s > 0$ to all $s \notin \mathbb{Z}$ by means of the formula

$$M(s)\sum_n a_n\varepsilon(s, n) = \sum_n a_n c(s, n)\varepsilon(s, n).$$

Now we can consider a new Hermitian form on $\mathcal{H}^\infty(s)$.

$$\mathcal{H}^\infty(s) \times \mathcal{H}^\infty(s) \to \mathbb{C}, \quad \langle f, g \rangle = \int_G f(x)M(s)\overline{g(x)}dx.$$ 

This has nothing to do with the Hilbert space inner product which is induced from the identification $H(s) \cong L^2(K)$. Even more, this new Hermitian form needs not to be positive definite in general.

We can consider also the subspaces $\mathcal{H}^\infty, \text{even}(s) = \mathcal{H}^\infty(s) \cap \mathcal{H}^{\text{even}}(s)$ and similarly for odd. The formula in Proposition 4.4 shows that these subspaces are $G$-invariant.

4.5 Lemma. Assume $s \in (-1, 1), s \neq 0$. The Hermitian form $\langle f, g \rangle$ on $\mathcal{H}^{\text{even}}(s)$ is positive definite. The action of $G$ on $\mathcal{H}^{\text{even}}(s)$ is unitary.

Assume $s \in (-1, 1)$. We denote by $\tilde{H}^{\text{even}}(s)$ the Hilbert space which is obtained from $\mathcal{H}^{\text{even}}(s)$ through completion.

4.6 Proposition (Complementary series). For each $s \in (-1, 1), s \neq 0$, the representation of $G$ on $\tilde{H}^{\text{even}}(s)$ is a (continuous) unitary representation. The functions $\varepsilon(s, n)$, $n$ even, define an orthonormal basis.
5. The discrete series

Möbius transformations
Let
\[ g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}(2, \mathbb{C}) \]
be a complex invertible $2 \times 2$-matrix. Denote by $\hat{\mathbb{C}} = \mathbb{C} \cup \{\infty\}$ the Riemann sphere. The transformation
\[ g(z) = \frac{az + b}{cz + d} \]
is defined first outside a finite set of $\hat{\mathbb{C}}$ but can be extended to a bijection $\hat{\mathbb{C}} \rightarrow \hat{\mathbb{C}}$. This is an action of $\text{GL}(2, \mathbb{C})$ on $\hat{\mathbb{C}}$ from the left. It is well known and easy to check that the subgroup $\text{SL}(2, \mathbb{R})$ acts on the upper half plane $\mathcal{H}$. It is also well known that the Cayley transformation
\[ \sigma = \begin{pmatrix} 1 & -i \\
1 & i \end{pmatrix} \]
maps the upper half plane unto the unit disk. The inverse transformation is given by
\[ \sigma^{-1} = \frac{1}{2i} \begin{pmatrix} i & i \\
-1 & 1 \end{pmatrix}. \]
As a consequence the group
\[ \sigma \text{SL}(2, \mathbb{R})\sigma^{-1} \]
acts on the unit disk $\mathcal{E}$. This group is also a well-known classical group. We denote by $U(1, 1)$ the unitary group of signature $(1, 1)$ that is defined through
\[ g'Jg = J \quad \text{where} \quad J = \begin{pmatrix} 1 & 0 \\
0 & -1 \end{pmatrix}. \]
The special unitary group of signature $(1, 1)$ is
\[ \text{SU}(1, 1) = U(1, 1) \cap \text{SL}(2, \mathbb{C}). \]
One can check
\[ \text{SU}(1, 1) = \sigma \text{SL}(2, \mathbb{R})\sigma^{-1}. \]
A very quick proof rests on the fact that a $2 \times 2$-matrix $g$ has determinant 1 if and only if
\[ g'Ig = I \quad \text{where} \quad I = \begin{pmatrix} 0 & -1 \\
1 & 0 \end{pmatrix}. \]
Hilbert spaces of holomorphic functions

5.1 Lemma. Let \( U \subset \mathbb{C} \) be an open subset and \( K \subset U \) a compact subset. There exists a constant \( C \) such that every holomorphic function satisfies the inequality

\[
|f(a)|^2 \leq C \int_U |f(z)|^2 \, dz \quad \text{for } a \in K.
\]

Here \( dz = dx dy \) denotes the standard Lebesgue measure.

Proof. There exists \( r > 0 \) such that for each \( a \in K \) the closed disk of radius \( r \) around \( a \) is contained in \( U \). We consider the Taylor expansion

\[
f(z) = \sum_{n=0}^{\infty} a_n (z - a)^n.
\]

By means of

\[
\int_{x^2+y^2 \leq r^2} z^m \bar{z}^n = 0 \quad \text{for } m \neq n
\]

we obtain

\[
\int_U |f(z)|^2 \, dz \geq \int_{|z-a| \leq r} |f(z)|^2 = \sum_{n=0}^{\infty} \int_{|z-a| \leq r^2} |a_n z^n| \geq \pi r^2 |f(a)|^2.
\]

We can take \( C = \pi^{-1} r^{-2} \).

5.2 Proposition. Let \( U \subset \mathbb{C} \) be an open subset and \( h: U \to \mathbb{R} \) an everywhere positive continuous function. Consider the measure \( d\omega = h(z) \, dz \). Then

\[
L^2_{\text{hol}}(U, d\omega) = \{ f \in L^2(U, d\omega, \quad \text{f holomorphic}) \}
\]

is a closed subspace of \( L^2(U, d\omega) \) and hence a Hilbert space.

Proof. Let \( (f_n) \) be a sequence in \( L^2_{\text{hol}}(U, d\omega) \) that converges to \( f \) in the Hilbert space \( L^2(U, d\omega) \). We have to show that \( f \) is holomorphic. This is true since Lemma 5.1 shows that the sequence converges locally uniformly.

We denote by \( \mathcal{H} \) the upper half plane in the complex plane. Recall that the group \( G = \text{SL}(2, \mathbb{R}) \) acts on \( \mathcal{H} \) through \((az + b)(cz + d)^{-1}\). The measure \( dx dy / y^2 \) is invariant under the action of \( G \). We consider more generally for integers \( n \) the measures

\[
d\omega_n = y^n \frac{dx dy}{y^2}
\]

Then we consider the space

\[
H_n = L^2_{\text{hol}}(\mathcal{H}, d\omega_n)
\]

of all holomorphic functions which are square integrable with respect to this measure. We know that this is a Hilbert space. We define an action \( \pi_n \) of \( G = \text{SL}(2, \mathbb{R}) \) on function on \( \mathcal{H} \) by means of the formula

\[
(\pi_n(g)f)(z) = f(g^{-1}z)(cz + d)^{-n}.
\]

This defines a unitary representation of \( G \).
5.3 Proposition. The Hilbert space $H_n = L^2_{\text{hol}}(\mathcal{H}, d\omega_n)$ is different from 0 if $n \geq 2$. The formula

$$(\pi_n(g)f)(z) = f(g^{-1}z)(cz + d)^{-n}$$

defines a unitary representation of $G = \text{SL}(2, \mathbb{R})$ on $H_n$.

Proof. It remains to show that $H_n$ is not zero if $n \geq 2$. For this transform the measure $d\omega_n$ to the unit disk $\mathcal{E}$ by means of the Cayley transformation $w = (z - i)(z + i)^{-1}$. Its inverse is $z = i(1 + w)(1 - w)^{-1}$. The imaginary part $y$ of $z$ transforms as

$$y = \frac{1 - |w|^2}{|1 - w|^2}.$$ 

The formula

$$\frac{dz}{dw} = \frac{-2i}{(1 - w)^2}$$

shows that the Euclidian measure $dxdy$ transforms as

$$d\nu = \frac{4}{|1 - w|^4}dudv$$

where $dudv$ is the Euclidean measure of $\mathcal{E}$. This means that $H_n$ can be identified with the space of all holomorphic functions

$$f : \mathcal{E} \rightarrow \mathbb{C}, \quad \int_{\mathcal{E}} |f(w)|^2 \left(\frac{1 - |w|^2}{|1 - w|^2}\right)^{n-2} d\nu < \infty$$

It is called the holomorphic discrete series. If one considers antiholomorphic instead of holomorphic functions one obtains the antiholomorphic discrete series.

6. The space $S_{m,n}$

We consider the groups

$$G = \text{SL}(2, \mathbb{R}) \quad \text{and} \quad K = \text{SO}(2, \mathbb{R}).$$

Making use of the Iwasawa decomposition, we can write any function $f : G \rightarrow \mathbb{R}$ as functions of the variables $a, n, \theta$

$$f(g) = g(a, n, \theta).$$

Since $g$ can be considered as a function on $\mathbb{R}_{>0} \times \mathbb{R} \times \mathbb{R}$, it makes sense to talk about differentiable $g$ and in this way of differentiable $f$. We denote the subspace of differentiable functions of $C_c(G)$ by $C_c^\infty(G)$. 
The space $S_{m,n}$

6.1 Definition. The space $S_{m,n}$ consists of all $f \in C_\infty^c(G)$ with the property $\text{Smn}$

$$f(k_0 x k_\theta) = f(x) e^{-im\theta} e^{-in\theta'} \quad (x \in G).$$

Let be $f \in C_\infty^c(G)$. Then the Fourier coefficient $f_{m,n}(x) = \int_0^{2\pi} \int_0^{2\pi} f(k_0 x k_\theta) e^{-im\theta} e^{-in\theta'} d\theta d\theta'$ is contained in $S_{m,n}$. From the theory of Fourier series we obtain

$$f(x) = \sum_{m,n} f_{m,n}(x) e^{-im\theta} e^{-in\theta'}$$

where the convergence is absolute and locally uniform in $x$. Let $\text{supp}(f)$ be the support of $f$. Then $K \text{supp}(f)K$ contains the support of $f_{m,n}$. We have proved the following result:

6.2 Lemma. Let be $f \in C_\infty^c(G)$ and let be $\varepsilon > 0$. There exists a function $g$ which is a finite linear combination from functions contained in $S_{m,n}$ and with the following property:

a) $\text{supp}(g) \subset K \text{supp}(f)K$,

b) $|f(x) - g(x)| < \varepsilon$ for $x \in G$.

Corollary. The algebraic sum $\sum_{m,n} S_{m,n}$ is dense in the space $L^1(G, dx)$ with respect to the norm $\| \cdot \|_1$.

Here $dx$ of course is a Haar measure. Recall that $G$ is a unimodular group, hence we have to define

$$f^*(x) = \overline{f(x^{-1})}.$$

We study the convolution.

6.3 Lemma. We have $\text{FaltSmn}$

a) $S_{m,n} \ast S_{p,q} = 0$ if $n \neq p$.

b) $S_{m,n} = S_{n,m}$.

c) $S_{m,n} \ast S_{n,q} \subset S_{m,q}$.

The proof can be given by an easy calculation. We restrict to the case a). In the convolution integral

$$(f \ast g)(x) = \int_G f(y) g(y^{-1} x) dy$$

we replace $y$ by $y k_\theta$ which doesn’t change the integral. Now we use the transformation properties of $f$ and $g$ and obtain that $(f \ast g)(x)$ remains unchanged if one multiplies it by $e^{2\pi (p-n)\theta}$, This proves a).

From Lemma 6.3 we see that $S_{n,n}$ is a star algebra.
6.4 Proposition. *The algebra* $S_{n,n}$ *is commutative.*

Proof. There is a very general principle behind this statement. It depends on the fact that $G = \text{SL}(2, \mathbb{R})$ admits two involutions

$$x^\tau = x' \quad \text{(transpose of } x)$$

$$x^\sigma = \gamma x \gamma$$

where $\gamma = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$. We collect the properties of the two involutions that are needed in the proof.

1) $\sigma$ is an automorphism $((xy)^\sigma = x^\sigma y^\sigma)$ and $\tau$ is an anti-automorphism $((xy)^\tau = y^\tau x^\tau)$.

2) $k^\tau = k^\sigma = k^{-1}$ for $k \in K$.

3) Every element of $G$ can be written as product $sk$ of a symmetric matrix $(s = s^\tau)$ and an element $k \in K$.

4) For every symmetric $s = s^\tau$ there exist $k \in K$ such that

$$s^\sigma = ksk^{-1}$$

for all symmetric $s = s^\tau$.

1) and 2) are clear. To prove 4) we use that any real symmetric matrix $s$ can be transformed by means of an orthogonal matrix into a diagonal matrix

$$k_1sk_1^{-1} = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}.$$ 

Here $\lambda_1, \lambda_2$ are the eigen values of $s$. Since we can replace $k_1$ by $\gamma k_1$ we can assume that the determinant of $k_1$ is 1. The matrix $s^\sigma$ is also symmetric and has the same eigen values as $s$. Hence we find an orthogonal matrix $k_2$ of determinant 1 such that

$$k_2s^\sigma k_2^{-1} = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}.$$ 

We obtain $ksk^{-1} = k^\sigma$ where $k = k_2^{-1}k_1$. Finally we prove 2). So, let $x \in \text{SL}(2, \mathbb{R})$. We consider $xx'$. This is a symmetric positive definite matrix. Transformation to a diagonal matrix by means of an orthogonal matrix gives a symmetric positive matrix $s$ with the property $xx' = s^2$. Then $k = s^{-1}x$ is orthogonal and has the desired property. This finishes the proof of 1)-4).

We also mention that the Haar measure on $G$ is invariant under the two involutions. We give the argument for the anti-automorphism $\sigma$. The integral $\int_G f(x^\sigma)dx$ is right invariant. Since $G$ is unimodular it agrees with $\int_G f(x)dx$ up to a positive constant factor $C$. Since $\sigma$ is involutive we get $C^2 = 1$ and hence $C = 1.$
Now we can give the proof of Proposition 6.4. We extend the involutions to functions on $G$ by

$$f^\sigma(x) = f(x^\sigma), \quad f^\tau(x) = f(x^\tau).$$

We claim the following two formulae:

$$(f * g)^\sigma = f^\sigma * g^\sigma, \quad (f * g)^\tau = g^\tau * f^\tau.$$  

We prove the second formula (the first one is similar). We have

$$(f * g)^\tau(x) = \int_G f(y)g(y^{-1}x^\tau)dy \quad \text{and} \quad (g^\tau * f^\tau)(x) = \int_G g(y^\tau)f((y^{-1})^\tau x)dy.$$  

In the first integral we replace $y$ by $y^\tau$, then $y$ by $xy$ and after that $y$ by $y^{-1}$. This transformations don’t change the integrals and proves the claimed identity.

Now we assume that $f \in S_{m,m}$. In this case we claim $f^\tau = f^\sigma$. To prove this we write $x \in G$ in the form $x = sk$. Then we get

$$f^\tau(x) = f(k^\tau s) = \varrho(k)f(s) \quad (\varrho(k) = e^{im\theta})$$

and

$$f^\sigma(x) = f(s^\sigma k^{-1}) = \varrho(k)f(s^\sigma) = \varrho(k)f(\gamma s^\gamma^{-1}) = f(k)f(s).$$

Now let $f, g$ be both in $S_{m,m}$. Then $f * g$ is in $S_{m,m}$ too and we get $(f * g)^\tau = (f * g)^\sigma$. This gives

$$g^\tau * f^\tau = f^\sigma * g^\sigma.$$  

In this formula we can replace $\tau$ by $\sigma$. Since $f, g \in S_{m,m}$ implies that $f^\sigma, g^\sigma \in S_{m,m}$ we can replace $f, g$ by $f^\sigma, g^\sigma$ to obtain the final formula $f * g = g * f$.  

Now we consider a Banach representation of $G = SL(2, \mathbb{R})$,

$$\pi : G \longrightarrow GL(H).$$

We assume that $H$ is a Hilbert space. But it is not necessary to assume that it is unitary. We restrict this representation to $K$. Without loss of generality we can assume that the restriction to $K$ is unitary (use Proposition I.7.9). We consider the (closed) subspace

$$H(n) := \{ h \in H; \quad \pi(k_\theta)(h) = e^{im\theta}h \}.$$  

The spaces $H(n)$ are pairwise orthogonal and that $H$ is the direct Hilbert sum of the $H(n)$. For an element $h$ in the algebraic sum, we denote by $h_n$ the component in $H(n)$.  

6.5 Lemma. The space $S_{m,n}$ maps $H(n)$ into $H(m)$. It maps $H(q)$ to zero if $n \neq q$.

The proof is very easy and can be omitted. □

6.6 Proposition. Assume that $\pi : G \to GL(H)$ is an irreducible representation on a Hilbert space. The algebra $S_{m,m}$ acts topologically irreducibly on $H(m)$ if this space is not zero.

Proof. Let $h \in H(m)$ be a non-zero element. We want to show that $S_{m,m}h$ is dense in $H(m)$. (This means that $S_{m,m}$ acts topologically irreducible on $H(m)$.) We consider the space $Ah$. We know that $Ah$ is a dense subspace of $H$. It is contained in the algebraic sum $\sum H(n)$. We consider the projection of $\sum H(n)$ to $H(m)$. The image of $Ah$ under this projection is dense in $H(m)$. Lemma 6.5 shows that this image equals $S_{m,m}h$. This shows that $S_{m,m}$ acts topologically irreducible on $H(m)$. □

Since $S_{m,m}$ is abelian, we now obtain the following theorem.

6.7 Theorem. Let $\pi : G \to GL(H)$ be an irreducible representation on a Hilbert space. We assume that the restriction to $K$ is unitary. Then $H$ is the direct Hilbert sum of the spaces $H(n)$. Assume that $H(n)$ is finite dimensional. Then $\dim H(n) \leq 1$. This is always the case if $\pi$ is unitary.

We just mention that this a special case of a more general result that holds for any semi simple Lie group $G$ and a maximal compact subgroup. Examples are $G = SL(n, \mathbb{R})$, $K = SO(n, \mathbb{R})$. For every irreducible unitary representation of $G$ the $K$-isotypic components are finite dimensional. In other words: each irreducible unitary representation of $K$ (which is always finite dimensional) occurs with finite multiplicity in $\pi|K$. The proof more involved, mainly since $K$ is not commutative in general.

A vector $h \in H$ is called $K$-finite, if the space generated by all $\pi(k)h$ is finite dimensional. The space of $K$-finite vectors is denoted by $H_K$. The elements of $H_{m,n}$ are $K$-finite. Since every finite dimensional representation of a compact group is completely reducible, we obtain the following description.

6.8 Lemma. Let $\pi$ be a Banach representation of $G$ on a Hilbert space $H$ such that the restriction to $K$ is unitary. Then

$$H_K = \sum_{m \in \mathbb{Z}} H(m) \quad \text{(algebraic sum)}.$$

It is important to describe for a given irreducible unitary representation $\pi$ the set of all $n$ such such that $H(n)$ is different from zero (and then one-dimensional). For this we look for operators that shift $H(n)$ which means that $H(n)$ is mapped into another $H(m)$. We will find such operators in the Lie algebra.
7. The Lie-algebra of the special linear group of degree two

A (finite dimensional real or complex algebra) is a finite dimensional real or complex vector space together with a \((\mathbb{R}-\text{or } \mathbb{C})\)-bilinear map \(g \times g \to g\). Every complex algebra has an underlying real algebra. There is an obvious notion of homomorphism of real or complex algebras and there is an obvious notion of cartesian product of two (real or complex) algebras \(g_1 \times g_2\). The product has to be taken componentwise.

\[
[(A_1, B_1), (A_2, B_2)] = ([A_1, A_2], [B_1, B_2]).
\]

An algebra \(g\) is called a real or complex Liealgebra if there exists an injective \(\mathbb{R}-\text{or } \mathbb{C}\)-linear map \(g \to \mathbb{C}^{n \times n}\) such that the multiplication corresponds to the Lie bracket

\[
[A, B] = AB - BA.
\]

We recall the exponential function for matrices \(A \in \mathbb{C}^{(n, n)}\):

\[
\exp(A) = \sum_{n=0}^{\infty} \frac{A^n}{n!}.
\]

It is clear that this series converges absolutely. The rule

\[
B^{-1} \exp(A)B = \exp(B^{-1}AB)
\]

is trivial. We need also the rule

\[
\det \exp(A) = \exp(\text{tr}(A))
\]

which can be reduced to diagonal matrices (using the previous rule and the fact that the set of all matrices with \(n\) pairwise different eigenvalues is dense in the set of all matrices).

The rule

\[
\exp(A + B) = \exp(A) + \exp(B)
\]

holds if \(A, B\) commute. There are generalizations to the case where \(A, B\) do not commute. To get them on considers

\[
\log(\exp(tA) \exp(tB))
\]

This is defined when \(tA, tB\) are in a sufficiently small neighborhood of the origin. It can be expanded for given \(A, B\) and sufficiently small \(t\) into a power series. One can compute

\[
\log(\exp(tA) \exp(tB)) = tA + tB + \frac{1}{2} t^2 [A, B] + \cdots
\]
or
\[
\exp(tA) \exp(tB) = \exp\left( tA + tB + \frac{1}{2} t^2 [A, B] + \cdots \right)
\]
This formula is a link between the multiplication in the group and the Lie bracket.

Let \( G \subset \text{GL}(n, \mathbb{C}) \) be a closed subgroup. We consider the set \( g \) of all matrices \( A \) such that \( \exp(tA) \in G \) for all \( t \in \mathbb{R} \). It can be shown that \( g \) is a real Lie-algebra. (This does not exclude that in some cases it is a complex Liealgebra.) This means that \( g \) is a real vector space and that \( A, B \in g \) implies that \( [A, B] \in g \). There is no need to give a proof, since in all cases that we treat this will be clear. One can show that
\[
\exp : g \longrightarrow G
\]
is a local homeomorphism at the origin. We do not need this general theory, since these facts can be verified directly in all cases that we need.

**Some Liealgebras**

We associate to each group \( G \) in the list
\[
\text{GL}(n, \mathbb{C}), \text{SL}(n, \mathbb{C}), \text{GL}(n, \mathbb{R}), \text{SL}(n, \mathbb{R}), \text{O}(p,q), \text{SO}(p,q), \text{U}(p,q), \text{SU}(p,q)
\]
their Liealgebra \( g \)
\[
\begin{align*}
gl(n, \mathbb{C}) &= \mathbb{C}^{n \times n}, \\
\mathfrak{sl}(n, \mathbb{C}) &= \{ A \in \text{gl}(n, \mathbb{C}), \quad \text{tr}(A) = 0 \}, \\
gl(n, \mathbb{R}) &= \mathbb{R}^{n \times n}, \\
\mathfrak{sl}(n, \mathbb{R}) &= \{ A \in \text{gl}(n, \mathbb{R}), \quad \text{tr}(A) = 0 \}, \\
o(p,q) &= \{ A \in \text{gl}(n, \mathbb{R}), \quad A^t E_{p,q} + E_{p,q} A = 0 \}, \\
so(p,q) &= \mathfrak{o}(p,q) \cap \mathfrak{sl}(p + q, \mathbb{R}), \\
u(p,q) &= \{ A \in \text{gl}(n, \mathbb{C}), \quad \bar{A}^t E_{p,q} + E_{p,q} A = 0 \}, \\
su(p,q) &= \mathfrak{u}(p,q) \cap \mathfrak{sl}(p + q, \mathbb{C}).
\end{align*}
\]
These are vector spaces which admit the bilinear pairing
\[
\mathfrak{g} \times \mathfrak{g} \longrightarrow \mathfrak{g}, \quad (A, B) \longmapsto [A, B] = AB - BA.
\]
In all these cases there is a map
\[
\exp : \mathfrak{g} \longrightarrow G, \quad \exp(A) = e^A.
\]
We formulate a general fact which is rather clear in our cases.
7.1 Lemma. In all cases above, the map \( \exp : \mathfrak{g} \to G \) is locally topological at 0, i.e. it maps a suitable small open neighborhood of \( 0 \in \mathfrak{g} \) onto a small open neighborhood of the unit element in \( G \).

Proof. The proof is very easy. One constructs an inverse of the exponential map by means of a matrix logarithm

\[
-\log(E - A) = \sum_{n=1}^{\infty} \frac{A^n}{n}
\]

which converges in a small neighborhood of \( A = 0 \).

From now on we restrict to \( G = \text{SL}(2, \mathbb{R}) \). In this case we have

\[
\mathfrak{g} = \{ A \in \mathbb{R}^{(2,2)}; \; \text{tr}(A) = 0 \}.
\]

Besides \( \mathfrak{g} \) we need also its complexification

\[
\mathfrak{g}_\mathbb{C} := \{ A \in \mathbb{C}^{(2,2)}; \; \text{tr}(A) = 0 \}.
\]

This is a complex Lie algebra (i.e. it is a complex vector space and invariant under the Lie-bracket).

Finally we mention another result which is important in this connection.

7.2 Lemma. The group \( G = \text{SL}(2, \mathbb{R}) \) is generated by any neighborhood of the unit element.

The following proof works for every connected group. (That \( \text{SL}(2, \mathbb{R}) \) is connected follows from the Iwasawa decomposition). Let \( U \) be a an open neighborhood of the identity. By continuity the set of all \( a \) such that \( a \) and \( a^{-1} \) is contained in \( U \) is also an open neighborhood. Hence we can assume that \( a \in U \) implies \( a^{-1} \in U \). We consider the image \( U(n) \) of

\[
U^n \to G, \quad (a_1, \ldots, a_n) \mapsto a_1 \cdots a_n.
\]

The union \( G_0 \) of all \( U(n) \) is an open subgroup of \( G \). Since \( G \) is the disjoint union of cosets of \( G_0 \), the complement of \( G_0 \) in \( G \) is also open. Hence \( G_0 \) is open and closed in \( G \) and hence \( G_0 = G \) since \( G \) is connected.
8. The derived representation

Differential calculus usually is defined for maps \( U \to \mathbb{R}^m \), where \( U \subset \mathbb{R}^n \) is an open subset. There is a straight forward generalization where \( E = \mathbb{R}^n \) and \( F = \mathbb{R}^m \) are replaced by Banach spaces, where in this context they are understood as Banach spaces over the field of real numbers. It is clear what this means. A map \( f : U \to F \) in this context is called differentiable at \( a \in U \) if there exists a continuous (real) linear map \( L_a : E \to F \) such that

\[
f(x) - f(a) = L_a(x - a) + r(x) \quad \text{where} \quad \lim_{x \to a} \frac{\|r(x)\|}{\|x - a\|} = 0.
\]

If this is true for every \( a \in U \) we call \( f \) differentiable. Then we can consider the derivative

\[
Df : U \to \text{Hom}(E, F), \quad df(a) = L_a.
\]

Since the subspace of bounded operators of \( \text{Hom}(E, F) \) is a Banach space too, we can ask for differentiability of \( df \). In this way one can define the space of infinite differentiable functions \( C^\infty(U, F) \). As in the finite dimensional case, the chain rule holds for (infinitely often) differentiable functions. We also mention that a continuous linear map is differentiable by trivial reasons.

We want apply this to functions \( G \to H \) where \( H \) is a Banach space (as usual over the complex numbers). Assume that \( \pi : G \to \text{GL}(H) \) be a continuous representation. We associate to an arbitrary vector \( h \in H \) a function \( G \to H, \ x \mapsto \pi(x)h \).

We call the vector \( h \) differentiable if this function is infinitely often differentiable. We denote the space of differentiable vectors by \( H^\infty \). These is a sub-vector space. It depends of course on \( \pi \). Hence, for example, \( H_\pi^\infty \) is a more careful notation.

We give examples of a differentiable vector.

8.1 Lemma. Let \( \pi : G \to \text{GL}(H) \) be a Banach representation and \( f \in C_0^\infty(G) \). Then the image of \( \pi(f) \) is contained in \( H^\infty \). As a consequence the space \( H^\infty \) is a dense subspace of \( H \).

Corollary. Assume that \( H \) is a Hilbert space and that the restriction of \( \pi \) to \( K \) is unitary. Let \( m \) be an integer such that \( \dim H(m) \leq 1 \). Then the elements of \( H(m) \) are differentiable. (This applies if \( \pi \) is an irreducible unitary representation.)

Proof. The first part follows from the formula

\[
\pi(x)\pi(f)v = \int_G f(y)\pi(x)\pi(y)vdy = \int_G f(x^{-1}y)\pi(y)dy
\]
by means of the Leibniz rule that allows to interchange integration and integration. (Of course we need a Banach valued version of the rule. We omit a proof of this, since it can be done as in the usual case.)

To prove the corollary we observe that $\pi(S_{m,n})H(m)$ is dense in $H(m)$ by Proposition 6.6. In the case that $H(m)$ is finite dimensional it is the whole of $H(m)$. Now we can apply the first part of the proof. 

Let $X \in \mathfrak{g}$ and $h \in H^{\infty}$. The map

$$\mathbb{R} \longrightarrow H, \quad t \longmapsto \pi(\exp(tX))h$$

is differentiable, since it is the composition of two differentiable maps. Hence we can define the operator $d\pi(X) : H^{\infty} \to H$:

$$d\pi(X)h := \frac{d}{dt}\pi(\exp(tX)h)\bigg|_{t=0}.$$ 

This is related to another construction, the Lie-derivative (from the left). This is for each $X \in \mathfrak{g}$ a map

$$\mathcal{L}_X : C^{\infty}(G,H) \longrightarrow C^{\infty}(G,H)$$

which is defined by

$$\mathcal{L}_X f(a) = \frac{d}{dt}f(a \exp(tX))\bigg|_{t=0}.$$ 

(It is easy to show that $\mathcal{L}_X f$ is differentiable.) The Lie-derivative has nothing to do with the representation $\pi$. But we get a link to the derived representation if we apply it to functions of the type $x \mapsto \pi(x)h$.

8.2 Lemma. Let $X \in \mathfrak{g}$ and $h \in H^{\infty}$. We consider the differentiable function $f(x) = \pi(x)h$ on $G$. Then the formula

$$\pi(a)d\pi(X)h = (\mathcal{L}_X f)(a)$$

holds, in particular

$$d\pi(X)h = (\mathcal{L}_X f)(e) \in H^{\infty}_\pi.$$ 

Proof. The second formula is just true by definition. The first one can be obtained if one applies $\pi(a)$ to the second one. One just has to observe that $\pi(a)$ commutes by continuity with the limit

$$\lim_{t \to 0} \pi(\exp(tX))h - h.$$ 

The Lie derivatives satisfy a basic commutation rule.
8.3 Proposition. For \( X, Y \in \mathfrak{g} \) the formula

\[
[L_{[X,Y]} = \mathcal{L}_X \circ \mathcal{L}_Y - \mathcal{L}_Y \circ \mathcal{L}_X \quad ([X,Y] = XY - YX)
\]

holds.

Proof. The formula states

\[
\frac{d}{dt} f(\exp(t[X,Y]))\big|_{t=0} = \frac{d}{dt} \frac{d}{ds} \left( f(\exp(tX)\exp(sY)) - f(\exp(tY)\exp(sX)) \right)\big|_{t=s=0}.
\]

Here \( f \) is a \( C^\infty \) function on some open neighborhood of the unit element of \( G = \text{SL}(2,\mathbb{R}) \). It is easy to show that \( f \) is the restriction of a \( C^\infty \)-function on some open neighborhood of the unit element of \( \text{GL}(2,\mathbb{R}) \) (which can be considered as an open subset of \( \mathbb{R}^4 \)). Hence it is sufficient to prove the formula for \( G = \text{GL}(2,\mathbb{Z}) \) and \( \mathfrak{g} \) can be replaced with the space of all real \( 2 \times 2 \) matrices. Using Taylor’s formula one can reduce the proof to the case where \( f \) is a polynomial. The product rule shows that the formula is true for \( f g \) if it is true for \( f \) and \( g \). Hence it is sufficient to prove it for linear functions. So we reduced the statement to the formula

\[
\frac{d}{dt} \exp(t[X,Y])\big|_{t=0} = \frac{d}{dt} \frac{d}{ds} \left( \exp(tX)\exp(sY) - \exp(tY)\exp(sX) \right)\big|_{t=s=0}.
\]

This is equivalent to the formula \([X,Y] = XY - YX\) \( \square \).

As a consequence of the commutation rule of the Lie derivative we obtain the following for the derived representation.

8.4 Proposition. Let \( \pi : G \to \text{GL}(H) \) be a unitary representation. Then the following rule

\[
d\pi([X,Y]) = d\pi(X) \circ d\pi(Y) - d\pi(Y) \circ d\pi(X)
\]

holds.

Propositions 8.3 and 8.4 provide special cases of the following definition.

8.5 Definition. Let \( \mathcal{A} \) be an associative algebra (over the field of real numbers is enough). A map \( \varphi : \mathfrak{g} \to \mathcal{A}, \mathfrak{A} \mapsto \mathcal{A} \) is called a Lie homomorphism if it is \( \mathbb{R} \)-linear and if

\[
\varphi([A,B]) = \varphi(A)\varphi(B) - \varphi(B)\varphi(A)
\]

holds.
Hence Proposition 8.3 provides a Lie homomorphism
\[ g \mapsto \text{End}(C^\infty(G, H)) \]
and Proposition 8.4 a Lie homomorphism
\[ g \mapsto \text{End}(H^\infty). \]

In both cases the algebra on the right-hand side is a complex algebra (since \( H \) is a complex vector space and since we understand by \( \text{End} \) complex linear endomorphisms. In such a case we can extend \( \varphi \) to the complexification \( g_\mathbb{C} \) by means of the formula
\[ g_\mathbb{C} \mapsto A, \quad \varphi(A) = \varphi(\text{Re}(A)) + i\varphi(\text{Im}(A)). \]

It is easy to check that the formula
\[ \varphi([A, B]) = \varphi(A)\varphi(B) - \varphi(B)\varphi(A) \]
remains true where the bracket in \( g_\mathbb{C} \) is of course defined by the formula
\[ [A, B] = AB - BA. \]

9. Explicit formulae for the Lie-derivatives

In the following we use the elements
\[ X = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad W = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad V = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \]
of \( g \). Three of them give a basis of \( g \). We also will consider the complexification \( g_\mathbb{C} \). Here we use the (complex) basis
\[ W, \quad E^- = H - iV, \quad E^+ = H + iV. \]

So we have
\[ E^- = \begin{pmatrix} 1 & -i \\ -i & -1 \end{pmatrix}, \quad E^+ = \begin{pmatrix} 1 & i \\ i & -1 \end{pmatrix}. \]

Recall that the Lie-derivatives to \( g_\mathbb{C} \) can be extended by \( \mathbb{C} \)-linearity:
\[ \mathcal{L}_{A+iB} = \mathcal{L}_A + i\mathcal{L}_B, \]

since \( H \) and hence \( C^\infty(G, H) \) is a complex vector space.
From the Iwasawa decomposition we know that we can write \( g \in G \) in the form
\[
g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} \sqrt{y} & \sqrt{y}^{-1} x \\ 0 & \sqrt{y}^{-1} \end{pmatrix} \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix}
\]
with unique \( x \) and \( y > 0 \). The angle \( \theta \) is determined mod \( 2\pi \). We need the expressions for \( x, y, \theta \) in terms of \( a, b, c, d \). To get them it is useful to use complex numbers. Let \( \tau \) be a complex number in the upper half plane, \( \text{Im} \tau > 0 \). Since \( c, d \) are real but not both zero, the number \( c\tau + d \) is different from zero. Hence we can define
\[
g(\tau) = \frac{a\tau + b}{c\tau + d}.
\]
Let \( h \) be a second matrix from \( G \). A direct computation which we omit shows
\[
(gh)(\tau) = g(h(\tau)).
\]
We also notice
\[
g_0(i) = i.
\]
Hence we obtain
\[
\frac{ai + b}{ci + d} = x + iy.
\]
This gives us \( x \) and \( y \) in terms of \( a, b, c, d \).
\[
y = \frac{1}{c^2 + d^2}, \quad x = \frac{ac + bd}{c^2 + d^2}.
\]
Looking at the second row of the Iwasawa decomposition we get
\[
c\sqrt{y} = -\sin \theta, \quad d\sqrt{y} = \cos \theta.
\]
This shows
\[
e^{i\theta} = \cos \theta + i \sin \theta = \frac{d - ic}{\sqrt{c^2 + d^2}}.
\]
This gives as
\[
\theta = \text{Arg} \frac{d - ic}{\sqrt{c^2 + d^2}}.
\]
Since \( \theta \) is only determined mod \( 2\pi \), we have to say a word about the choice of the argument \( \text{Arg} \). All what we need is that for a given \( g_0 \in G \) one can make the choice of \( \text{Arg} \) such it depends differentiably on \( g \) for all \( g \) in a small open neighborhood of \( g_0 \).

In the following we will fix \( g \in G \) and \( X \in \mathfrak{g} \) and consider
\[
g(t) = g \exp(tX)
\]
§9. Explicit formulae for the Lie-derivatives

for small \( t \). We write \( x(t), y(t), \theta(t) \) in this case. As we mentioned the function \( \theta(t) \) can be chosen for small \( t \) such that it depends differentially on \( t \). If we insert \( t = 0 \) we get the original \( x, y, \theta \).

For the Lie-derivative we have to consider a differentiable function \( f \) on \( G \). We can write it as function \( f \) of three variables. We get

\[
    f(g(t)) = F(x(t), y(t), \theta(t)).
\]

By means of the chain rule we get

\[
    \frac{d}{dt} f(g(t)) = \frac{\partial F}{\partial x} \dot{x}(t) + \frac{\partial F}{\partial y} \dot{y}(t) + \frac{\partial F}{\partial \theta} \dot{\theta}(t).
\]

Recall that we have to evaluate this expression at \( t = 0 \) to get the Lie derivative.

As an example we take

\[
    X = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad e^{tX} = \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}.
\]

Then we have

\[
    g(t) = \begin{pmatrix} a & b + ta \\ c & d + tc \end{pmatrix}.
\]

We obtain

\[
    z(t) = \frac{ai + at + b}{ci + ct + d}.
\]

Differentiation and evaluating at \( t = 0 \) gives

\[
    \dot{z}(0) = \frac{1}{(ci + d)^2}.
\]

Using the formulae

\[
    y = \frac{1}{c^2 + d^2}, \quad e^{2i\theta} = \frac{(d - ic)^2}{c^2 + d^2}
\]

we obtain

\[
    \dot{z}(0) = ye^{2i\theta} \quad \text{or} \quad \dot{x}(0) = y \cos 2\theta, \quad \dot{y}(0) = y \sin 2\theta.
\]

Finally, to compute \( \dot{\theta}(0) \), we use the formula

\[
    \cos \theta(t) = (d + ct) \sqrt{y(t)}.
\]

Differentiation gives

\[
    -\dot{\theta}(t) \sin \theta(t) = (d + ct) \frac{\dot{y}(t)}{2\sqrt{y(t)}} + c \sqrt{y(t)}.
\]
Evaluating by \( t = 0 \) we get
\[
\dot{\theta}(0) \sin \theta = \frac{d\dot{y}(0)}{2\sqrt{y}} - c\sqrt{y}.
\]

We insert \(-c\sqrt{y} = \sin \theta\) and \(\dot{y}(0) = y \sin 2\theta = 2y \sin \theta \cos \theta\) to obtain
\[
\dot{\theta}(0) = -d \sqrt{y} \cos \theta + 1 = -\cos^2 \theta + 1 = \sin^2 \theta.
\]

Another – even easier example – is \(L_W\). A simple computation gives
\[
W = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \exp tW = \begin{pmatrix} \cos t & \sin t \\ -\sin t & \cos t \end{pmatrix}.
\]

Hence we obtain that \(L_W\) is given by the operator \(\partial/\partial \theta\). In a similar way other elements of the Lie algebra can be treated. Since \(V = 2X - W\) we get \(L_V\). We omit the computation for
\[
H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad e^{tH} = \begin{pmatrix} e^t & 0 \\ 0 & e^{-t} \end{pmatrix}
\]
and just collect the formulae together.

9.1 Proposition. Let \(f \in C^\infty\) and \(A \in \mathfrak{g}\). We denote by \(F(x,y,\theta)\) the corresponding function in the coordinates and similarly \(G(x,y,\theta)\) for \(g = L_A f\).

The operator \(F \mapsto G\) can be described explicitly as follows:
\[
\mathcal{L}_X = y \cos 2\theta \frac{\partial}{\partial x} + y \sin 2\theta \frac{\partial}{\partial y} + \sin^2 \theta \frac{\partial}{\partial \theta},
\]
\[
\mathcal{L}_W = \frac{\partial}{\partial \theta},
\]
\[
\mathcal{L}_V = 2y \cos 2\theta \frac{\partial}{\partial x} + 2y \sin 2\theta \frac{\partial}{\partial y} - \cos 2\theta \frac{\partial}{\partial \theta},
\]
\[
\mathcal{L}_H = -2y \sin 2\theta \frac{\partial}{\partial x} + 2y \cos 2\theta \frac{\partial}{\partial y} + \sin 2\theta \frac{\partial}{\partial \theta},
\]
and, as a consequence,
\[
\mathcal{L}_E^- = -2ye^{-2i\theta} \left( \frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right) + ie^{-2i\theta} \frac{\partial}{\partial \theta}.
\]
10. Analytic vectors

Let $E$, $F$ be Banach spaces over the field of real numbers and let $U \subset E$ be an open subset. We introduced the notion of a differentiable map $U \to F$. In the case that $E$ is finite dimensional (but $F$ may be not) we can also define the notion of an analytic map. In the case $E = \mathbb{R}^n$ this means as usual that for each $a \in U$ there exists a small neighborhood in which there exists an absolutely convergent expansion as power series

$$f(x) = \sum_{\nu \in \mathbb{N}_0^n} a_{\nu} (x_1 - a_1)^{\nu_1} \cdots (x_n - a_n)^{\nu_n} \quad (a_{\nu} \in F).$$

This notion is invariant under linear transformation of the coordinates, hence it carries over to arbitrary $E$. We denote by $C^\omega(U,F)$ the space of all analytic functions. This is a subspace of $C^\infty(U,F)$. The basic property of analytic functions is the principle of analytic continuation. Assume that $U$ is connected and that $a \in U$ a point that all derivatives of $f$ of arbitrary order vanish (this is understood to include $f(a) = 0$). Then $f$ is identically zero.

Using the standard coordinates of $G$, we can define the notion of analytic function $G \to H$ into any Banach space. If $\pi : G \to \text{GL}(H)$ is a representation we can define the notion of an analytic vector $h \in H$. By definition this means that the function $\pi(x)h$ on $G$ is analytic. The set $H^\omega$ of all analytic vectors is a sub-vector space of $H^\infty$.

We recall the formula for the Lie-derivative

$$[L_X f](y) = \frac{d}{dt} f(y \exp(tX))\bigg|_{t=0}.$$

We replace $y$ by $y \exp(uX)$ and obtain

$$[L_X f](y \exp(uX)) = \frac{d}{du} f(y \exp((u + t)X))\bigg|_{t=0} = \frac{d}{du} f(y \exp(uX)).$$

By induction follows

$$[L_X^n f](y \exp(uX)) = \frac{d^n}{du^n} f(y \exp(uX)).$$

The Taylor expansion of the function $t \mapsto f(y \exp(tX))$ is given by

$$f(y \exp(tX)) = \sum_{n=0}^{\infty} \frac{1}{n!} \frac{d^n}{dt^n} f(y \exp(tX))\bigg|_{t=0} t^n = \sum_{n=0}^{\infty} \frac{1}{n!} [L_X^n f](y) t^n.$$

This formula is true for given $X, y$ if $|t|$ is sufficiently small, $|t| < \varepsilon$. For a real constant the formula $L_cX = cL_X$ can be checked. This shows that (for fixed $y$) the Taylor formula holds if $X$ is in a sufficiently small neighborhood of the origin. We specialize the Taylor expansion to the function $f(x) = \pi(x)h$ and to $t = 1$. 

10.1 Proposition. Let \( h \in H \) be an analytic vector. For sufficiently small \( X \) the formula
\[
\pi(\exp(X))h = \sum_{n=0}^{\infty} \frac{1}{n!} d\pi(X)^n h
\]
holds.

Making use of Lemma 7.1 and Lemma 7.2 we now obtain the following important result.

10.2 Proposition. Let \( \pi : G \to GL(H) \) be a Banach representation and let \( V \subset H \) be a linear subspace consisting of analytic vectors that is invariant under \( d\pi(g) \). Then the closure of \( V \) is invariant under \( G \).

In the next section we will prove the existence of analytic vectors.

11. The Casimir operator

In the following we will make use of the basic commutation rules in \( \mathfrak{g} \):
\[
[E^+, E^-] = -4iW, \quad [W, E^+] = 2iE^+, \quad [W, E^-] = -2iE^-.
\]
They can be verified by direct computation.

Let \( \mathcal{A} \) be an associative \( \mathbb{C} \)-algebra and
\[
\varrho : \mathfrak{g} \to \mathcal{A}
\]
be a Lie homomorphism, i.e. a linear map with the property
\[
\varrho([A, B]) = \varrho(A)\varrho(B) - \varrho(B)\varrho(A).
\]
We also can consider its \( \mathbb{C} \)-linear extension \( \mathfrak{g}_\mathbb{C} \to \mathcal{A} \). Our typical example is that \( \mathcal{A} \) is the algebra of (algebraic) endomorphisms of an abstract (complex) vector space \( \mathcal{H} \). In this case we talk about a Lie-algebra representation of \( \mathfrak{g} \) on \( \mathcal{H} \). We denote the image of element \( A \in \mathfrak{g}_\mathbb{C} \) by the corresponding bold letter \( \mathbf{A} \). We define the Casimir element by
\[
\omega = H^2 + V^2 - W^2.
\]
Using the above commutation rules we can check by a simple computation
\[
\omega = H^2 + V^2 - W^2 = E^+ E^- + 2iW - W^2.
\]
The basic property of the Casimir element is that it commutes with the image of \( \mathfrak{g}_\mathbb{C} \).
11.1 Lemma. The Casimir element $\omega$ (with respect to $\varrho : \mathfrak{g} \to \mathfrak{A}$) commutes with all $\mathfrak{A}$ for $\mathfrak{A} \in \mathfrak{g}$.

Proof. One uses the second formula for the Casimir operator and applies the above commutation rules.  

The Lie algebra $\mathfrak{g}$ acts on the space $C^\infty(G, H)$. Hence we can consider the Casimir operator $\omega$ acting on this space. Using the formulae on Proposition 8.2 we get the explicit expression

$$\omega = 4y^2 \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) - 4y \frac{\partial}{\partial x} \frac{\partial}{\partial \theta}.$$  

We are especially interested on its action of functions of the type

$$f(xk) = e^{in\theta} f(x).$$  

Since $\partial f/\partial \theta = in f$ we see that the operator

$$4y^2 \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) - 4yn \frac{\partial}{\partial x}$$

has the same effect on $f$ as the Casimir operator. The advantage of the latter operator is that it is – like the Laplace operator – an elliptic differential operator. We make use of a basis result that $C^\infty$-eigen functions $Df = \lambda f$ of an elliptic differential operator $D$ are analytic functions. Usually this theorem is formulated for scalar valued function. But it is also true for Banach valued functions. For this one can use for example the following general result.

11.2 Proposition. A function $f : G \to H$ is analytic if and only if $L \circ f$ is analytic for every continuous linear function $L$.  

We do not give a proof.

Let now $\pi : G \to \text{End}(H)$ a Banach representation and let $h \in H$ by a differentiable vector. Then there is the Casimir operator acting on $H^\infty$. Assume that $h$ is an eigen vector and that $h \in H(m)$. We claim that $h$ is an analytic vector. We have to show that the function $f_h(x) = \pi(x)h$ is analytic. The condition $h \in H(m)$ implies

$$f_h(xk) = e^{in\theta} f_h(x).$$  

For any $A \in \mathfrak{g}$ we have

$$L_A f_h = f_{d\pi(A)h}.$$  

This carries over to the Casimir operator. So we can write

$$\omega f_h = f_{\omega h}.$$  

By assumption $h$ is an eigen vector of the Casimir operator. This implies that $f_h$ is an eigen function. So we get that $f_h$ is analytic. By definition this means that $h$ is analytic. This gives the following result.
11.3 Proposition. Let $\pi : G \to \text{GL}(H)$ be a Banach representation and let $h \in H(m)$ be a differentiable vector which is an eigen vector of the Casimir operator. Then $h$ is analytic.

This gives us the possibility to identify many analytic vectors. For this we have to study the action of the generators of $\mathfrak{g}$ on the spaces $H(m)$ in more detail.

11.4 Lemma. Let $\pi : G \to \text{GL}(H)$ be a Banach representation on a Hilbert space $H$. We assume that the restriction to $K$ is unitary. We also assume that the elements of $H(m)$ are differentiable. Then $d\pi(W)$ acts on $H(m)$ by multiplication by $\text{im}$. The operators $d\pi(E^+)$ maps $H(m)$ to $H(m+2)$ and $d\pi(E^-)$ maps $H(m)$ to $H(m-2)$.

Proof. Recall that the space $H$ is the direct Hilbert sum of the $K$-isotypical components, which are $H(m)$. A direct computation gives

$$\exp(tW) = \begin{pmatrix} \cos t & \sin t \\ -\sin t & \cos t \end{pmatrix}.$$ 

This gives

$$\pi(\exp(tW))h = e^{imt}h \quad \text{for} \quad h \in H(m).$$

If we differentiate by $t$ and evaluate than by $t = 0$ we get the desired result for the action of $W$.

To get the statement for the action of $E^+$ we use the rule

$$d\pi(W)d\pi(E^+) = d\pi[W,E^+] + d\pi(E^+)d\pi(W)$$

and the commutation rule $[W,E^+] = 2iE^+$. For a vector $a \in H(m)$ we get

$$d\pi(W)d\pi(E^+)h = i(m+2)d\pi(E^+)h.$$ 

Hence $d\pi(E^+)h$ is an eigen value of $d\pi(W)$ with eigenvalue $i(m+2)$. Hence it must lie in $H(m+2)$. The argument for $E^-$ is similar. $\Box$

From the second formula for the Casimir we see that $H(m)$ is mapped into itself. This gives the following basic result.

11.5 Theorem. Let $\pi : G \to \text{GL}(H)$ be an unitary representation such that all $H(m)$ have dimension $\leq 1$. (This is the case if $\pi$ is irreducible). Then the vectors from $H_K = \sum H(m)$ (algebraic sum) are analytic and this space is invariant under $\mathfrak{g}$.

Proof. Since the spaces $H(m)$ have dimension $\leq 1$ they consist of differentiable vectors. The elements of $H(m)$ are eigen elements of the Casimir operator. $\Box$
By a representation of the Lie algebra $\mathfrak{g}$ on the abstract vector space $E$ we understand a Lie homomorphism map $\pi : \mathfrak{g} \to \text{End}(E)$, i.e. a linear map with the property
$$\pi([X,Y]) = \pi(X) \circ \pi(Y) - \pi(Y) \circ \pi(X).$$

For a unitary representation $\pi : G \to \text{GL}(H)$ we can consider the derived representation $d\pi : \mathfrak{g} \to \text{End}(H)$.

11.6 Proposition. Let $\pi : G \to \text{GL}(H)$, be a unitary representation such that all $H(m)$ have dimension $\leq 1$. Then $\pi$ is irreducible if and only if the derived representation $d\pi : \mathfrak{g} \to \text{End}(H_K)$ has the following property. Let $A$ be the algebra of operators that is generated by the image of $\mathfrak{g}$ and by the identity. For each non-zero $h$ which is contained in some $H(m)$ we have $A(h) = H_K$.

Proof. We notice that the set $A(h) = \{A(h), A \in A\}$ is a vector space. This vector space can also be described as follows. Let $X = X_1 \cdots X_n$ be an operator such that each $X_i$ is one of the $d\pi(E^+)$, $d\pi(E^-)$, $d(W)$. Then $A(h)$ is the vector space generated by all $X(h)$.

For a $X$ as above the space $X(C_h)$ is either 0 or it is one of the $H(n)$. Hence we see that $A(h)$ is generated by certain spaces $H(n)$.

Now we assume that $\pi$ is irreducible. We prove that $A(h)$ is the full $H_K$. We argue indirectly. So we can assume that there exist an $H(n) \neq 0$ which is not contained in $A(h)$. We recall that the spaces $H(k)$ are pairwise orthogonal. Hence the preceding remark shows that $H(n)$ is orthogonal to $A(h)$. But then $H(n)$ is orthogonal to the closure of $A(h)$. We know that this space is invariant under $G$. But this is not possible since we assumed that $\pi$ is not the trivial one dimensional representation.

Assume now that $A(h) = H_K$ for all nonzero $h \in H(m)$. We claim that $\pi$ is irreducible. Again we argue indirectly. We find a proper closed invariant subspace $H'$. We can take a non-zero isotypic component $H'(m)$. Consider a non-zero element $h \in H'(m)$. By assumption then $A(h)$ is $H_K$. This shows $H_K \subset H'$ and hence $H = H'$.

Since the Casimir operator commutes with all elements of $\mathfrak{g}$ we obtain the following kind of a Schur lemma.

11.7 Proposition. Let $\pi : G \to \text{GL}(H)$ be an irreducible unitary representation. Then the Casimir operator acts on $H_K$ by multiplication by some constant.

This constant is a basic invariant of $\pi$. 

12. Admissible representations

Let $\pi : G \to \text{Un}(H)$ be a unitary representation of $G = \text{SL}(2, \mathbb{R})$. Then we can consider the space of $K$-finite vectors $H = H_K$. They consist of differentiable vectors. The Liealgebra $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{R})$ acts on them. The action of $K$ and $\mathfrak{g}$ are tied together.

**12.1 Remark.** Let $\pi : G \to H$ be a unitary representations of $G$. Then on $H_K$ the following formula holds,

$$\pi(k) \circ d\pi(X) = \pi(kXk^{-1}) \circ \pi(k), \quad X \in \mathfrak{g}, \ k \in K.$$

**Corollary.** This formula shows that $\mathfrak{g}$ acts on $H_K$.

The action of $\mathfrak{g}$ extends $\mathbb{C}$-linearly to the complexification $\mathfrak{g}_\mathbb{C} = \mathfrak{sl}(2, \mathbb{C})$. We are led to consider the following algebraic objects.

**12.2 Definition.** A $\mathfrak{g}$-$\mathcal{K}$-module $H$ is a complex vector space $H$ together with a homomorphism

$$\pi : K \longrightarrow \text{GL}(H)$$

and a Lie-homomorphism

$$d\pi : \mathfrak{g} \longrightarrow \text{End}(H)$$

such the compatibility relation

$$\pi(k) \circ d\pi(X) = \pi(kXk^{-1}) \circ \pi(k), \quad X \in \mathfrak{g}, \ k \in K$$

is valid. Furthermore, let $H(m)$ be the eigenspace

$$H(m) = \{h \in H; \quad \pi(k_\theta) = e^{im\theta} h\},$$

then $H$ is the algebraic direct sum of all $H(m)$.

So each unitary irreducible representation induces a $\mathfrak{g}$-$\mathcal{K}$-module. Even more, it is admissible in the following sense.

**12.3 Definition.** A $\mathfrak{g}$-$\mathcal{K}$-module $H$ is called admissible if the eigenspaces $H(m)$ are finite dimensional.
12.4 Definition. An admissible $\mathfrak{g}$-$K$-module $\mathcal{H}$ is called irreducible, if it is not the zero representation and if the following condition is satisfied. Let $\mathcal{A}$ be the $\mathbb{C}$-algebra of operators that is generated by the image of $\mathfrak{g}$. For each non-zero $h$ which is contained in some $\mathcal{H}(m)$, we have $\mathcal{A}(h) = \mathcal{H}$.

It is clear what an isomorphism of admissible representation means. We emphasize that this is understood in a pure algebraic way. As we have seen, every irreducible unitary representation $G \to \text{GL}(H)$ has an underlying irreducible admissible $\mathfrak{g}$-$K$-module. We also recall that the Lie homomorphism can be extended $\mathbb{C}$-linearly to $\mathfrak{g}_C$.

We study in detail admissible representations. For this we will use the basis $E^+, E^+, W$ for $\mathfrak{g}_C$. We recall

$$[E^+, E^-] = -4iW, \quad [W, E^+] = 2iE^+, \quad [W, E^-] = -2iE^-.$$ 

We mention that $W$ acts by multiplication with $i$ on $\mathcal{H}(n)$. The same argument as in Lemma 11.4 shows $E^+(\mathcal{H}(n)) \subset \mathcal{H}(n + 2), \quad E^-(\mathcal{H}(n)) \subset \mathcal{H}(n - 2)$.

We notice that the operators $E^+ E^-$ act on $\mathcal{H}(n)$. We consider the $\mathbb{C}$-algebra generated by all operators from $\text{End}(\mathcal{H}(n))$ generated by $E^+ E^-$ and by multiplications with scalars. It is rather clear that this acts irreducible on $\mathcal{H}(n)$. These operators commute with the Casimir operator. Hence the Casimir operator $\omega = E^+ E^- + 2iW - W^2$ acts on $\mathcal{H}(n)$ by multiplication with a scalar. It follows that $E^+ E^-$ acts as scalar.

12.5 Theorem. Let $\mathcal{H}$ be an irreducible admissible $\mathfrak{g}$-$K$-module. Then $\dim \mathcal{H}(n) \leq 1$.

Choose some $h \in \mathcal{H}(n)$, $h \neq 0$ for suitable $n$. We know that the Casimir operator $\omega$ acts as scalar on $h$. Then also $E^+ h, E^- h, Wh$ are eigenvectors of $\omega$ with the same eigenvalue. The irreducibility shows that $\omega$ acts with the same scalar on the whole $\mathcal{H}$.

12.6 Theorem. Let $\mathcal{H}$ be an irreducible admissible $\mathfrak{g}$-$K$-module. Then the Casimir operator acts by multiplication with a constant on $\mathcal{H}$.

Now we study in detail the irreducible unitary representations. We see that the spaces

$$H^{\text{even}} = \sum_{n \text{ even}} \mathcal{H}(n), \quad H^{\text{odd}} = \sum_{n \text{ odd}} \mathcal{H}(n)$$

are invariant subspaces. Hence we have to distinguish between an even case (all $\mathcal{H}(2n + 1)$ are zero) and an odd case (all $\mathcal{H}(2n)$ are zero).

Let $S$ be a set of all integers which are all odd or all zero. We call $S$ an interval if for $m, n \in S$ each number of the same parity between $m$ and $n$ is
contained in $S$. We claim now that the set $S$ of all $n$ such that $H(n) \neq 0$ is an interval. To prove this we consider an $n \in S$ such that $H(n)$ is different from zero. Recall that $H(n)$ is one-dimensional. We choose a generator $h$. The space $H$ is generated by all $A_1 \ldots A_m h$ where $A_i \in \mathfrak{g}_C$. From the relations between the generators we see that $H$ is generated by $E^+_m h$ and $E^-_m h$. Let for example $H(n + 2k) = 0$, $k > 0$. Then $E^{n+2k}_h = 0$ and hence all $H(m)$, $m > n + 2k$, are zero. Hence $S$ is an interval.

12.7 Proposition. For the set $S$ of integers $m$ with the property $H(m) \neq 0$ of an admissible representation there are the following possibilities:

1) $S$ is the set of all even integers.
2) $S$ is the set of all odd integers.
3) There exists $m \in S$ such that $S$ consists of all $x \geq m$ with the same parity.
4) There exists $n \in S$ such that $S$ consists of all $x \leq n$ with the same parity.
5) There exist integers $m \leq n$ of the same parity such that $S$ consists of all $x \in \mathbb{Z}$, $m \leq x \leq n$, of the same parity.

In the cases 3)-5) we call $m$ the lowest weight and the non-zero elements of $H(m)$ the lowest weight vectors. Similarly we call $n$ the highest weight.

We study case 1) in more detail. We choose a non-zero vector $h \in H(0)$. We know that $E^+$ is non zero on all $H(n)$ ($n$ even). Hence we can define for all even $n$ a uniquely determined $h_n \in H(n)$ such that

$$h_0 = h, \quad E^+ h_n = h_{n+2}.$$ 

Then we define the number $c_n \neq 0$ by

$$E^- h_n = c_n h_{n-2}.$$ 

The system of numbers $(c_n)_{n \text{ even}}$ is independent of the choice of $h$. It is clear that the action of $\mathfrak{g}_C$ is determined by this system of numbers and it is also clear that isomorphic representations lead to the same system. A much better result is true. The relation $[E^+, E^-] = -4iW$ shows

$$c_n - c_{n+2} = 4n, \quad c_0 = \lambda$$ 

Hence all $c_n$ are determined by one, for example by $c_0$. This equals the eigenvalue $\lambda$ of the Casimir operator, actually

$$\omega h = (E^+ E^- + 2iW - W^2) h = \lambda h = c_0 h \quad \text{for} \quad h \in H(0).$$

Hence we obtain in the case 1)

$$c_{2n} = \lambda - 4(n-1)n$$
(and \( c_n = 0 \) for odd \( n \)). So the representation is determined up to isomorphism by \( \lambda \). What can we say about the existence? We start with some complex number \( \lambda \). We can take for each even \( n \) a one dimensional vector space \( \mathbb{C} h_n \), then define the vector space \( \mathcal{H} = \bigoplus \mathbb{C} h_{2n} \). The we can take the above formulas to define \( E^+, E^-, W \). It is easy to check that this gives a representation. Obviously this is an admissible representation if all \( c_{2n} \) are different from zero.

In this way we obtain the following result.

**12.8 Proposition.** An irreducible admissible representation of type 1) (in Proposition 12.7) is determined up to isomorphism by the eigenvalue \( \lambda \) of the Casimir operator. An eigenvalue \( \lambda \) occurs if and only if it is different from \( 4(n-1)n \) for all integers \( n \).

The case 2) is very similar. Here we choose a non-zero vector \( h \in H(1) \). Then we define for all odd \( n \) \( h_n \), such that \( h_1 = h \) and \( E^+ h_n = h_{n+2} \). Then we define \( c_n \) through \( E^- h_n = c_n h_{n-2} \). Then one gets

\[
\begin{align*}
c_1 &= \lambda + 1, \\
c_n - c_{n+2} &= 4n.
\end{align*}
\]

Here the solution is

\[
c_{2n+1} = \lambda - 4(n-1)n + 1
\]

(and \( c_n = 0 \) for even \( n \)).

**12.9 Proposition.** An admissible representation of type 2) (in Proposition 12.7) is determined up to isomorphism by the eigenvalue \( \lambda \) of the Casimir operator. An eigenvalue \( \lambda \) occurs if and only if it is different from \( 4(n-1)n+1 \) for all integers \( n \).

Assume now that there is a lowest weight \( m \). Now we choose a non-zero \( h \in H(m) \) and define \( h_m = h \) and \( E^+ h_k = h_{k+2} \) for \( k \geq n \) (same parity as \( n \)). They are all different from 0. Then we define the constants \( c_k, k \leq n \), through \( E^- h_k = c_k h_k \) for \( k \geq m \). We have \( E^- E^+ h_m = c_m h_m \) and \( E^- h_m = 0 \). Hence the relation \([E^+, E^-] = -4iW\) gives

\[
c_m = -4m \quad \text{and} \quad c_{k-2} - c_k = 4k \quad \text{for} \quad k > m.
\]

The only solution is

\[
c_k = -4 \sum_{\substack{\nu \leq k \leq s \leq k \\text{ and} \\nu \mod 2}} \nu \quad (k \geq m).
\]

**12.10 Proposition.** An admissible representation with a lowest weight vector is determined up to isomorphism by its lowest weight \( m \). An integer occurs as lowest weight if and only if \( m > 0 \).

We also mention that the eigenvalue of the Casimir operator is

\[
\lambda = m^2 - 2m.
\]

The same argument works if there is a highest weight vector.
12.11 Proposition. An admissible representation with a highest weight vector but no lowest weight vector is determined up to isomorphism by its highest weight \( n \). An integer occurs as highest weight if and only if \( n < 0 \).

In this case the eigenvalue of the Casimir operator is

\[
\lambda = n^2 + 2n.
\]

It remains to treat the case where a lowest weight \( m \) and a highest weight \( n \) exist. The are the only finite dimensional cases. In this case we get for the eigenvalue of the Casimir operator

\[
\lambda = n^2 + 2n = m^2 - 2m.
\]

This (and \( m \leq n \)) imply \( m = -n \) and \( n \geq 0 \). Hence we get the following result.

12.12 Proposition. An irreducible admissible \( g-K \)-module is finite dimensional if and only if it has a lowest weight \( m \) and a highest weight \( n \). These have the property \( m = -n, n \geq 0 \). It is determined by \( n \) up to isomorphism. Its dimension is \( n + 1 \). Hence it is determined as by its dimension. Every integer \( n \geq 0 \) occurs. The eigenvalue of the Casimir operator is \( n^2 - n \).

We mention that the trivial representation occurs here (\( m = n = 0 \)).

We can describe the finite dimensional irreducible admissible \( g-K \) modules in slightly modified form as follows. We write \( n = 2l \). Here \( l \) is a nonnegative integer or half integer. Then the dimension is \( 2l + 1 \). The above description shows that there exists a basis

\[
e_{l,-l}, e_{l,-l+1}, \ldots, e_{l,l-1}, e_{l,l}
\]

such that

\[
k_{\theta} e_{l,k} = e^{2\pi i k \theta} e_{k}.
\]

This implies

\[
W e_{l,k} = 2i e_{l,k}.
\]

Moreover

\[
E^+ e_{l,k} = e_{k+1}, \quad -l \leq k < l
\]

and

\[
E^- e_{l,k+1} = e_{l,k} e_{l,k}, \quad -l \leq k < l, \quad c_k = -8 \sum_{-l \leq k < \nu, \nu \geq 1} \nu \quad (k \geq l).
\]

We collect the main result in a table.
§13. The Bargmann classification

For later purpose we look at the finite dimensional representations of \( g \) in some more detail. Here the assumptions can be weakened.

**12.13 Proposition.** For each integer \( n \geq 0 \) there exists one and up to isomorphism only one irreducible admissible \( g \)-\( K \)-module of dimension \( \dim H = n + 1 \). We write \( n = 2l \) where \( l \) is integral or half integral, \( l \geq 0 \) There exists a basis \( e_{l-1}, e_{l-1+1}, \ldots, e_{l-1}, e_{l}, e_{l+1}, \ldots \) with the following properties. The group \( K \) acts through \( k_{g} e_{l,k} = e^{2ik\theta} e_{k} \). The Lie algebra \( g \) acts through

\[
W e_{l,k} = 2i e_{l,k},
\]

\[
E^{+} e_{l,k} = e_{l,k+1}, \quad -l \leq k < l,
\]

\[
E^{-} e_{l,k+1} = c_{l,k} e_{l,k}, \quad -l \leq k < l, \quad c_{k} = -8 \sum_{-l \leq \nu \leq k} \nu (k \geq l).
\]

13. The Bargmann classification

Let \( \pi : G \rightarrow GL(H) \) be an irreducible unitary representations. Then the derived representation \( g_{\mathbb{C}} \rightarrow \text{End}(H_{K}) \) has the property that the operators \( d\pi(A) \) for \( A \in g \) are skew symmetric,

\[
\langle Ah, h' \rangle = -\langle h, Ah' \rangle.
\]

This follows immediately from the definition of the derived representation. It is clear that this formula extends to all \( A \in g_{\mathbb{C}} \) in the following way

\[
\langle Ah, h' \rangle = -\langle h, \bar{A}h' \rangle.
\]

Hence it is natural to ask for an admissible representation \( g_{\mathbb{C}} \) on \( H \) whether there exists a Hermitian scalar product on \( H \) such that the elements of \( g \) act skew-symmetrically.
**13.1 Definition.** An admissible representation is called unitarizable if there exists a Hermitian scalar product on $H$ such that

$$\langle Ah, h' \rangle = -\langle h, \bar{A}h' \rangle$$

for $A \in g_{\mathbb{C}}$.

We want to pick out in the list of all admissible representations the unitary ones.

**13.2 Proposition.** An admissible representation is unitarizable if and of one of the following conditions is satisfied.

1) Even case without lowest or highest weight: The eigenvalue $\lambda$ of the Casimir operator is real and $\lambda \geq 0$.
2) Odd case without lowest or highest weight: The eigenvalue $\lambda$ of the Casimir operator is real and $\lambda \geq 1$.
3) All representations with a lowest but no highest weight $m, m > 0$, are unitarizable.
4) All representations with a highest but no lowest weight $n, n < 0$, are unitarizable.
5) A finite dimensional admissible representation is unitarizable if and only if it is trivial.

**Proof.** We treat the case 1) since all other cases are similar. There is a non zero element $h \in H(0)$ and $E^+ E^- h = \lambda h$. From the condition that the real elements $A \in g$ act skew Hermitian we obtain the rule $\langle E^+ h, h' \rangle = -\langle h, E^- h' \rangle$ and hence

$$\langle E^- h, E^- h \rangle = -\langle h, -E^+ E^- h \rangle = -\langle h, \lambda h \rangle = -\bar{\lambda} \langle h, h \rangle.$$

It follows that $\lambda$ is real and negative. Assume conversely that this is the case. Then we define a scalar product on $K$ such that the $H(n)$ are pairwise orthogonal and such that $\langle h, h \rangle = 1$. Then we define $\langle E^+ h, E^+ h \rangle = 1$ and so on. The proof no should be clear. \qed

**13.3 Proposition.** Two unitary representations $\pi : G \rightarrow GL(H), \pi' : G \rightarrow GL(H')$ of $G = SL(2, \mathbb{R})$ are unitary isomorphic if and only if the underlying admissible representations are (algebraically) isomorphic.

**Proof.** Let $T : H_K \rightarrow H'(K)$ be an isomorphism of the admissible representations. We choose scalar products such that $g$ acts skew symmetric. We choose a non zero $h \in H$ which is contained in some $H(m)$. We normalize $h$ such that $\langle h, h \rangle = 1$. We set $h' = Th$. Without loss of generality we may assume that $\langle h', h' \rangle = 1$ since we can replace the scalar product of $H'$ by a multiple. Now we claim that $T$ preserves the scalar products. For the proof we Definition 12.4. It implies that $H_K$ is generated by all $A_1 \cdots A_n h$, where $A_i \in g$. 
§13. The Bargmann classification

So we have to show that $T$ preserves the scalar products for such elements. This is done by induction. We just explain the beginning to the induction to give the idea. Since $H(m)$ is one-dimensional and since the spaces $H(n)$ are pairwise orthogonal, we know all scalar products $\langle h, x \rangle$. Let $A \in \mathfrak{g}$. The formula $\langle Ah, x \rangle = -\langle h, Ax \rangle$ gives all scalar products $\langle Ah, x \rangle$. Proceeding in this way we get that all scalar products are determined (from $\langle h, h \rangle = 1$). The same calculation can be done in $H'$. In this way we can see that $T$ preserves the scalar products. Now we can extend to an isomorphism of Hilbert spaces $T : H \to H'$. From Proposition 10.1 in connection with the Lemmas 7.2 and 7.1 we obtain that $T$ preserves the action of $G$. □

The question arises whether each admissible representation can be realized by unitary representations of $G$ (in the sense that it is isomorphic to its derived representation).

13.4 Theorem. Each unitarizable admissible representation can be realized by an irreducible unitary representation.

Proof. In Sect. 3–5 of this chapter we gave several examples of unitary representations. It can be checked we will see this below that we obtain all unitarizable admissible representations. This gives the proof. We consider the representations $H(s)$ which have been described in Chap. I, Sect. 7.

13.5 Lemma. Let $f \in \mathcal{H}(s)$ be an element that is $C^\infty$ considered as function on the group $G$. Then the image of $f$ in $H(s)$ is a $C^\infty$-vector of the representation $\pi_s$ and we have

$$\mathcal{L}_X f = d\pi_s(X)f.$$

Proof. It is easy to check that $\mathcal{L}_X f$ has the transformation properties of functions from $\mathcal{H}(s)$. Since it is continuous it is contained in $\mathcal{H}(s)$. We have to show that

$$\lim_{t \to 0} \int_K \left| f(k \exp(tX)) - f(k) \right| \frac{\mathcal{L}_X f(k)}{t}^2 dk = 0.$$

by definition of $\mathcal{L}$ the integrand tends pointwise to 0. Using the mean-value theorem it is easy to show that the integrand is bounded for small $t$. Hence the Lebesgue limit theorem can be applied. □

The space $H(n, s)$ of all $K$-eigenfunctions which pick up the $n$th power of the standard character is one dimensional and generated by the function

$$\varphi \left( \begin{pmatrix} \sqrt{y} & 0 \\ 0 & \sqrt{y}^{-1} \end{pmatrix} \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \right) = y^{(s+1)/2} e^{i n \theta}.$$
We can use the formula in Proposition 9.1 to compute the derived representation. The result is

\[
\begin{align*}
d\pi_s(W)\varphi_n &= i n \varphi_n, \\
d\pi_s(E^-)\varphi_n &= (s + 1 - n)\varphi_{n-2}, \\
d\pi_s(E^+)\varphi_n &= (s + 1 + n)\varphi_{n+2}.
\end{align*}
\]

From this description, it is easy to find invariant subspaces, namely

\[
H(s)_{\text{even}} = \bigoplus_{n \text{ even}} \mathbb{C} \varphi_n, \quad H(s)_{\text{odd}} = \bigoplus_{n \text{ odd}} \mathbb{C} \varphi_n.
\]

We first treat the even case. Then the parameter \( c \) from the previous section computes as \( c = (s + 1)(s - 1) \). This was the reason that we introduced already somewhat the parameter \( s \) as solution of this equation. We recall that the representation \( \pi_s \) is unitary if \( \text{Re} \, s = 0 \). We see that the corresponding derived representation is the even principal series. But one cannot realize the complementary series in this way, since this would demand \( s \in (-1, 1) \), \( s \neq 0 \). But in this case \( \pi_s \) is only a Banach representation. Hence one needs for the complementary series a different kind of realization. We indicated it in Chapt. I, Sect. 7. We will give more details.

The odd principal series is obtained completely from \( \pi_s \). Here the parameter \( c \) is computed as \( c = s^2 \) which again explains the conventions from the previous section. Hence in the case that \( s \) is purely imaginary but \( s \neq 0 \) in this way we get realizations of the two principal series where \( s = 0 \) has been excluded.

In the case \( s = 0 \) the odd space can be decomposed into subspaces again. We obtain in the case \( s = 0 \) two irreducible subspaces of the odd space,

\[
\bigoplus_{n \geq 1 \text{ odd}} \mathbb{C} \varphi_n, \quad \bigoplus_{n \leq 1 \text{ odd}} \mathbb{C} \varphi_n.
\]

Obviously they are realizations of the two mock discrete representations. So in this sense the mock discrete representations are simply degenerations of the principal series.

Hence we have found realizations of the principal series and the two mock discrete representations and we mention that the complementary series can also be realized by concrete unitary representations.

It remains to realize the discrete series. The holomorphic discrete series gives the discrete series with a lowest weight and the antiholomorphic discrete series gives the discrete series with a highest weight.

Collecting together, we get the classification of the irreducible unitary representations of \( G \). First we introduce some notations. Recall that in case 1)
and case 2) the representation is determined by a single parameter $\lambda$, the eigenvalue of the Casimir operator. Instead of $\lambda$ we will use a new parameter $s$. It is defined through

$$
\lambda = (s + 1)(s - 1)
$$

and is determined up to its sign.

1) $\lambda$ is real and $\lambda \leq -1$ if and only if $s$ is purely imaginary.

2) $\lambda$ is real and $-1 < \lambda < 1$ if and only if $s$ is real and $-1 < s < 1$, $s \neq 0$.

We use the following notations for irreducible unitary representations $\pi : G \to GL(H)$.

13.6 Definition. The even principal series consists of all representations of even type without highest or lowest weight and with the property that $s$ is purely imaginary. (Then $\lambda \leq -1$)

The complementary series consists of all representations of even type without highest or lowest weight and with the property that $s \in (-1, 1)$ but $s \neq 0$. (Then $-1 < \lambda < 0$)

The odd principal series consists of all representations of odd type without highest or lowest weight and with the property that $s$ is different from zero and purely imaginary (Here $\lambda \leq -1$.)

The holomorphic discrete series consists of all representations with a highest weight $n < -1$ and now lowest weight.

The antiholomorphic discrete series consists of all representations with a lowest weight $m > 1$ and now lowest weight.

The mock discrete series consists only of two representations, namely those with highest weight $m = -1$ (and no lowest weight) and conversely $n = 1$.

The border cases with highest weight $-1$ or lowest weight $1$ have some special properties. Hence they are separated from the other representations with a highest or lowest weight vector. Those with $m \leq -2$ or $n \geq 2$ define the discrete series and the two with $m = -1$ or $n = 1$ define the mock discrete series.

Collecting together we obtain Bargmann’s classification of all irreducible representations $\pi$ of $G$. If this representation is not the trivial one dimensional representation then $g$ acts non identically zero (Proposition 2.10.1) and then the derived representation is a unitarizable admissible representation. The above discussion gives now the main result.

13.7 Theorem. Each unitary irreducible unitary representation of $G = SL(2, \mathbb{R})$ is either the trivial one-dimensional representation or it is unitary isomorphic to a representation of the following list.

1) The even principal series, $s \in i\mathbb{R}$,

2) the odd principal series, $s \in i\mathbb{R} - \{0\}$,
3) the complementary series, $s \in (-1, 1) - \{0\}$.
4) the discrete series with highest weight $m \leq -2$ or lowest weight $n \geq 2$.
5) the mock discrete series (two representations, (highest weight $-1$ or lowest weight 1).

In the first three cases, $s$ is determined up to its sign. In the last two cases the weight is uniquely determined.

Why has the mock discrete series been separated from the discrete series? If $G$ is an arbitrary locally compact group, one has a general notion of a discrete series representation. An irreducible unitary representation is called a discrete series representation of it occurs (as unitary representation) in the regular representation $L^2(G)$. It can be shown that the discrete series representations of $G = \text{SL}(2, \mathbb{R})$ in this sense consist of all representations with a higher or lower weight vector with two exceptions, the weights 1 and $-1$ do not occur. Hence these play a special role. Since they look similar as the discrete series representations they are called “mock discrete”.

14. Automorphic forms

We consider a discrete subgroup $\Gamma \subset G$ with compact quotient $\Gamma \backslash G$. We recall that the representation of $G$ on $L^2(\Gamma \backslash G)$ is completely reducible with finite multiplicities. One can ask which representations of the Bargmann list occur and for their multiplicity. For this we make a simple remark.

14.1 Lemma. Let $f : \mathbb{H} \rightarrow \mathbb{C}$ be a function on the upper half plane and let $m$ be an integer. We consider the function

$$F \left( \begin{array}{cc} a & b \\ c & d \end{array} \right) = f \left( \frac{a_i + b}{c_i + d} \right) (c_i + d)^{-m}.$$ 

then we have

$$F(gk) = e^{im\theta} F(g)$$

and every function on $G$ with this transformation property comes from a function $f$ on $\mathbb{H}$. Moreover we can write $F$ as

$$F \left( \begin{array}{cc} \sqrt{y} & \sqrt{y}^{-1} x \\ 0 & \sqrt{y} \end{array} \right) \left( \begin{array}{cc} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{array} \right) = f(x + iy)e^{im\theta} \sqrt{y}^m.$$ 

The function $F$ is right-invariant under $\Gamma$ if and only if $f$ satisfies

$$f((az + b)(cz + d)^{-1}) = (cz + d)^m f(z)$$

for all elements in $\Gamma$. 
§15. Some comments on the Casimir operator

Proof. The proof is straight forward. □

Now we assume that there is an irreducible closed subspace $H \subset L^2(\Gamma \backslash G)$ which belongs to the holomorphic discrete series with lowest weight $m \geq 2$. If $h$ comes from a non-zero lowest weight vector $h$. From Lemma 14.1 we know that $h$ comes from a function $f : \mathbb{H} \to \mathbb{C}$ with the transformation property

$$f(az + b)(cz + d)^{-1} = (cz + d)^m f(z), \quad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma.$$ 

Since $h$ is a lowest weight vector we have $E^- h = 0$. Using the explicit formula for $E^-$ we obtain that

$$\left( \frac{\partial}{\partial x} + i \frac{\partial}{\partial y} \right) f = 0.$$ 

This means that $f$ is holomorphic. This means that $f$ is a holomorphic automorphic form. Conversely it can be shown that every holomorphic automorphic form occurs in this way.

But also other representations of the Bargmann list may occur. For example assume that an even principal series representation with parameter $s$ occurs. We can now consider a non-zero vector $h$ of weight 0. This is invariant under $K$ and corresponds to a function $f$ on the upper half plane. Recall that $h$ is an eigen form of the Casimir operator with eigen value $\lambda = (s+1)(s-1)$. Looking at the explicit expressions for $E^{\pm}$ we see that this means

$$y^2 \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) f = \lambda f.$$ 

What we have found is so-called wave form in the sense of Maass. Mass gave a generalization of the theory of modular forms replacing holomorphicity by certain differential equation. All these Maass forms can be recovered in the following way: Consider an irreducible sub representation $H \subset L^2(\Gamma \backslash G)$. Take a vector $h \in H(m)$ for an arbitrary $m$. By Lemma 14.1 this corresponds to function $f$ on $\mathbb{H}$ with a certain transformation property. Make use of the fact that $h$ is an eigen form of the Casimir operator. This produces a differential equation for $f$. In this way on recovers precisely the differential equations that Maass has introduced.

15. Some comments on the Casimir operator

Let $U \subset \mathbb{R}^n$ be an open subset. We are interested in maps

$$D : \mathcal{C}^\infty(U) \longrightarrow \mathcal{C}^\infty(U)$$
which can be written as finite sum
\[ Df = \sum h_{i_1 \ldots i_m} \frac{\partial^{i_1 + \cdots + i_m} f}{\partial x_1^{i_1} \ldots \partial x_n^{i_n}} \]
with differentiable coefficients \( h_{i_1 \ldots i_m} \). Clearly they are uniquely determined. We call \( D \) a linear differential operator. This notation is due to the fact that obviously \( D(f + g) = Df + Dg \) and \( D(Cf) = CDf \). When \( D \) is non-zero there exists a maximal \( m \) such that \( h_{i_1 \ldots i_m} \) is non-zero for some index with \( i_1 + \cdots + i_n = m \). We call \( m \) the degree of this operator and the function on \( U \times \mathbb{R}^n \)
\[ P(x_1, \ldots, x_n, X_1, \ldots, X_n) = \sum_{i_1 + \cdots + i_n = m} h_{i_1 \ldots i_m}(x) X_1^{i_1} \ldots X_n^{i_n} \]
is called the symbol of \( D \). This is a homogenous polynomial of degree \( m \) for fixed \( x \). The operator \( D \) is called elliptic, if it is not zero and if
\[ P(x, X) \neq 0 \quad \text{for all} \quad X \neq (0, \ldots, 0). \]
There are two simple observations:
a) Let \( V \subset U \subset \mathbb{R}^n \) be open subsets and let \( D \) be a linear differential operator on \( U \). Then there is a natural restriction to a linear differential operator on \( V \).
b) Let \( \varphi : U \rightarrow V \) be a diffeomorphism between open subsets of \( \mathbb{R}^n \) and let \( D \) be a linear differentiable operator on \( U \). Then the transported operator to \( V \) is a linear differential operator as well. Ellipticity is preserved.

It is clear how to define the notion of a linear differential operator on \( G = \text{SL}(2, \mathbb{R}) \) (use Iwasawa coordinates): We have seen that elements of \( \mathfrak{g} = \mathfrak{sl}(2, \mathbb{R}) \) acts on differentiable functions on \( G \) through
\[ Af(x) = \frac{d}{dt} f(x \exp(tA)) \big|_{t=0}. \]
It is clear that this is a linear differential operator on \( G \). This is a Lie homomorphism
\[ \mathfrak{g} \rightarrow \text{End}(\mathcal{C}^\infty(G)). \]
Here \( \mathcal{C}^\infty(G) \) denotes the space of all differentiable functions on \( G \) with values in some complex Banach space. So the space is a complex vector space and the Lie homomorphism can be extended \( \mathbb{C} \)-linearly to \( \mathfrak{g}_\mathbb{C} \). From construction it is clear that the images of \( \mathfrak{g} \) are left invariant operators, i.e. they commute with the operator “translation from the left”
\[ L_y : \mathcal{C}^\infty(G) \rightarrow \mathcal{C}^\infty(G), \quad (L_y f)(x) = f(yx). \]
We also can consider translation from the right
\[ R_y : \mathcal{C}^\infty(G) \rightarrow \mathcal{C}^\infty(G), \quad (R_y f)(x) = f(xy). \]

**Definition.** We denote by \( \mathcal{D}(G) \) the smallest subalgebra of \( \text{End}(\mathcal{C}^\infty(G)) \) that contains the image of \( \mathfrak{g} \).
It can be shown that $\mathcal{D}(G)$ equals the algebra of all left invariant linear differential operators: We don’t need this.

15.2 Definition. A Casimir operator is an element of $\mathcal{D}(G)$ that commutes with the image of $\mathfrak{g}$.

15.3 Lemma. Casimir operators $C$ have the property

$$R_g \circ C = C \circ R_g.$$  

Proof. Since the Casimir operators commute with $X \in \mathfrak{g}$ they also commute with $e^X$. But we know that $G$ is generated by the image of $\mathfrak{g}$.  

Hence Casimir operators are left and right invariant linear differential operators.
Chapter III. Representations of the Poincaré group

1. Unitary representations of some compact groups.

In this section we mention some results about the representation theory of the compact groups $U(n)$ and $SU(n)$. Here $U(n)$ denotes the group of all $n \times n$ matrices $A$ with the property $A^t A = E$ and $SU(n)$ denotes the subgroup of elements of determinant one. We want to describe the unitary irreducible representations of them.

We recall some facts for compact groups $K$:

1) Each irreducible unitary representation of a compact group is finite dimensional.
2) If $K \to GL(V)$ is a finite dimensional (continuous) representation of $K$, then there exists a Hermitian scalar product on $V$ such that the representation is unitary.
3) Let $K \to GL(V_i)$ be two finite dimensional irreducible unitary representations. They are unitary isomorphic if and only of the isomorphic in the usual sense.

Hence the classification of irreducible unitary representations of a compact group and the classification of finite dimensional irreducible representations is the same. So we can forget about the scalar products.

The representation theory of the group $SU(n)$ is closely related to the theory of rational representations of $GL(n, \mathbb{C})$. We have to consider polynomial functions $f$ on $GL(n, \mathbb{C})$. These are functions which can be written as polynomials in the $n^2$ variables $a_{ik}$. Moreover, a function $f$ on $GL(n, \mathbb{C})$ is called rational if there exists a natural number $k$ such that $(\det A)^k f(A)$ is polynomial. We mention the following result (which we will prove in the case $n = 2$).

1.1 Proposition. Every finite dimensional (continuous) representation $\pi : U(n) \to GL(V)$ extends to a rational representation. Two finite dimensional representations of $U(n)$ are isomorphic if and only if their rational extensions are isomorphic. The representation $\pi$ is irreducible if and only if its rational extension is irreducible.

Hence the classification of irreducible unitary representations of $U(n)$ is the same as the classification of irreducible rational representations of $GL(n, \mathbb{C})$. The classification of the irreducible rational representations can be given by their highest weight.
1.2 Theorem. Let $\pi : \text{GL}(n, \mathbb{C}) \rightarrow \text{GL}(V)$ be an irreducible rational representation. There exists a one-dimensional subspace $W \subset V$ that is invariant under all upper triangular matrices and $W$ is unique with this property. There exist integers $r_1 \geq r_2 \geq \cdots \geq r_n$ such that the action of diagonal matrices $A$ with diagonal $a_1, \ldots, a_n$ is given by 

$$\pi(A)w = a_1^{r_1} \cdots a_n^{r_n} w \quad (w \in W).$$

This gives a bijection between the set of isomorphy classes of irreducible rational representations of $\text{GL}(n, \mathbb{C})$ and the set of increasing tuples $r_1 \geq \cdots \geq r_n$ of integers.

We will not prove this result here.

The tuple $(r_1, \ldots, r_n)$ is called the highest weight and the elements of $W$ are called highest weight vectors.

This theorem does not tell, how the representations of a given highest can be constructed and, in particular, it does not tell the dimensions of the representations.

For us, the case $n = 2$ is of special importance. Let $l \in \{0, 1/2, 1, 3/2, \ldots\}$ be a non negative integral or half integral non-negative number. We consider the special $V_l$ of all polynomial functions $P : \mathbb{C}^2 \rightarrow \mathbb{C}$ which are homogenous and of degree $2l$. So the dimension of $V_l$ is $2l + 1$. We define a representation $

\rho_l : \text{GL}(2, \mathbb{C}) \rightarrow \text{GL}(V_l)$

by

$$(\rho(g)P)(x) = P(g'x).$$

(We use the standard action of $\text{GL}(2, \mathbb{C})$ on $\mathbb{C}^2$ of linear algebra which is an action from the left.) The subspace $W_l$ that is generated by the polynomial $P(x, y) = y$ is invariant under upper triangular matrices and it is the only one dimensional subspace with this property. From this one can deduce that $\rho_l$ is irreducible. The highest weight is $(0, 2l)$. More generally, we can consider the representation $\text{det}(g)^k \rho_l(g)$. Its highest weight is $(k, k + 2r)$. These pairs exhaust all highest weights. Hence we have found all representations of $\text{GL}(2, \mathbb{C})$ and as a consequence also of $\text{U}(2)$.

We are more interested in $\text{SU}(2)$. It is not difficult to show that every finite dimensional irreducible representation of $\text{SU}(2)$ is the restriction of a representation of $\text{U}(2)$. In this way one can prove the following result.
1.3 Theorem. The restriction of $\varrho_l$ to $SU(2)$ is irreducible. Every finite dimensional irreducible representation is isomorphic to one and only one representation $(V_l, \varrho_l)$.

Proofs in the case $n=2$

We study the group $SU(2)$. It consists of all complex matrices

$$\begin{pmatrix} a & b \\ -\bar{b} & \bar{a} \end{pmatrix}, \quad |a|^2 + |b|^2 = 1.$$  

This can be identified with the $3$-dimensional sphere $S_3$. We parameterize an open part of $SU(2)$ through

$$\{x = (x_1, x_2, x_3); x_1^2 + x_2^2 + x_3^2 < 1\} \rightarrow SU(2), \quad x \mapsto \begin{pmatrix} a & b \\ -\bar{b} & \bar{a} \end{pmatrix}.$$

$$a = x_1 + ix_2, \quad b = x_3 + \sqrt{1 - x_1^2 - x_2^2 - x_3^2}.$$  

Using this one can define when a function on this open subset of $S^3$ is differentiable or analytic. The functions are allowed to be Banach valued. Using similar maps we can introduce differentiable or analytic functions on any open subset of $SU(2)$. (The reader who is familiar with manifolds will see that there is a natural structure of a real analytic manifold on $SU(2)$.)

Let $\pi : SU(2) \rightarrow GL(H)$ be a continuous finite dimensional irreducible representation (on the complex vector space $H$). As in Chap. II, Sect. 8 we can define the subspace $H^\infty$ of differentiable vectors and we can define a derived representation

$$d\pi : \mathfrak{su}(2) \rightarrow \text{End}(H^\infty).$$

This is a Lie homomorphism in the sense of Definition II.8.5. The same proof also shows that $H^\infty$ is dense. Since $H$ is finite dimensional, this means that every vector of $H$ is differentiable. We will see more, namely that every vector is analytic. This is more difficult and needs some insight into the structure of $\mathfrak{g} = \mathfrak{su}(2)$. Therefore we consider $\mathfrak{su}(2)$ as subset of $\mathfrak{sl}(2, \mathbb{C})$. This is a real subspace. One checks

$$\mathfrak{sl}(2, \mathbb{C}) = \mathfrak{su}(2) \oplus i\mathfrak{su}(2).$$

And one checks that the Lie multiplication on $\mathfrak{sl}(2, \mathbb{C})$ is just the $\mathbb{C}$-bilinear extension of the Lie multiplication on $\mathfrak{su}(2)$. (In the notions of the next section this says that $\mathfrak{sl}(2, \mathbb{C})$ is the complexification of $\mathfrak{su}(2)$). In the same sense $\mathfrak{sl}(2, \mathbb{C})$ is also the complexification of $\mathfrak{sl}(2, \mathbb{R})$. So $\mathfrak{sl}(2, \mathbb{C})$ arises as complexification of two different Lie algebras.)

The representation extends $\mathbb{C}$-linearly to a Lie-representation

$$\pi : \mathfrak{sl}(2, \mathbb{C}) \rightarrow \text{End}(H).$$
We studied such representations in detail. In particular, we constructed a Casimir operator $\omega$ which commutes with all $A \in \mathfrak{sl}(2, \mathbb{C})$. Then it commutes also with $e^A$ and hence with all $g$ in a small neighbourhood of the unit element. Since $SU(2)$ is connected this neighbourhood generates the full group. Hence $\omega$ commutes with the full group $SU(2)$. Since the action is assumed to be irreducible, $\omega$ acts by a scalar on $H$.

We choose a basis of $\mathfrak{su}(2)$ and compute the exponentials

$$
X_1 = \frac{1}{2} \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad e^{2tX_1} = \begin{pmatrix} e^{it} & 0 \\ 0 & e^{-it} \end{pmatrix}
$$

$$
X_2 = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad e^{2tX_2} = \begin{pmatrix} \cos t & \sin t \\ -\sin t & \cos t \end{pmatrix}
$$

$$
X_3 = \frac{1}{2} \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \quad e^{2tX_3} = \begin{pmatrix} \cos t & i\sin t \\ i\sin t & \cos t \end{pmatrix}
$$

Notice that $2X_2 = W$ which we introduced earlier. The commutation relations are

$$
[X_1, X_2] = X_3, \quad [X_2, X_3] = X_1, \quad [X_3, X_1] = X_2.
$$

(This means that $\mathfrak{su}(2)$ is isomorphic to $\mathbb{R}^3$ with the cross product.) The expressions of $E^\pm$ in the $X_i$ are

$$
E^\pm = 2(\pm X_3 - iX_1).
$$

For the Casimir operator $\omega$ we get the expression

$$
\omega = E^+ E^- + 2iW - W^2 = -4(X_1^2 + X_2^2 + X_3^3).
$$

We compute the Lie derivatives

$$
(L_X(f))(x) = \frac{d}{dt} f(xe^{tX}) \bigg|_{t=0} \quad (X \in \mathfrak{su}(2))
$$

which transforms functions on $SU(2)$ (may be Banach valued) to functions of the same kind. We restrict the function $f$ to a function on the open ball

$$
\{(x_1, x_2, x_3); \ x_1^2 + x_2^2 + x_3^3 < 1\}
$$

through

$$
f_0(x_1, x_2, x_3) = f \left( \frac{a}{-b} \right), \quad a = x_1 + ix_2, \quad b = x_3 + ix_4,
\quad x_4 = \sqrt{1 - x_1^2 - x_2^2 - x_3^3}.
$$
One computes
\[ L_{X_1} = \frac{1}{2} \left[ -x_2 \frac{\partial}{\partial x_1} + x_1 \frac{\partial}{\partial x_2} + x_4 \frac{\partial}{\partial x_3} \right], \]
\[ L_{X_2} = \frac{1}{2} \left[ -x_3 \frac{\partial}{\partial x_1} - x_4 \frac{\partial}{\partial x_2} + x_1 \frac{\partial}{\partial x_3} \right], \]
\[ L_{X_3} = \frac{1}{2} \left[ -x_4 \frac{\partial}{\partial x_1} + x_3 \frac{\partial}{\partial x_2} - x_2 \frac{\partial}{\partial x_3} \right]. \]

We have proved that every vector of \( H \) is analytic. This implies, as in the case \( \text{SL}(2, \mathbb{R}) \), that the derived representation \( d\pi : \mathfrak{su}(2) \to \text{End}(V) \) is irreducible in the sense that every \( \mathfrak{su} \)-invariant subspace is \( V \) or 0. Notice that all subspaces of \( V \) are closed since \( V \) is finite-dimensional.

The representation \( d\pi \) extends \( \mathbb{C} \)-linearly to the complexification of \( \mathfrak{u}(2) \) which is \( \mathfrak{sl}(2, \mathbb{C}) \). This can be restricted to a Lie-homomorphism \( \mathfrak{sl}(2, \mathbb{R}) \to \text{End}(\mathcal{H}) \). Also \( \text{SO}(2) \) acts on \( H \), since it is a subgroup of \( \text{U}(2) \). This means that \( H \) is a \( \mathfrak{sl}(2, \mathbb{R}) \)-\( \text{SO}(2, \mathbb{R}) \)-module. For trivial reason it is admissible. Clearly it is irreducible. Such modules have been determined in Proposition II.12.12.

From the description that follows this proposition we see that there is exactly one such module for each dimension \( n \). This finishes the proof of Theorem 1.3.

1.4 Theorem. For each integer or half integer \( l \geq 0 \) there exists a unique irreducible unitary representation of \( \text{SU}(2) \) on a Hilbert space \( V_l \) of dimension \( 2l + 1 \). There exists a basis \( e_{l,-l}, e_{l,-l+1}, \ldots, e_{l,l-1}, e_{l,l} \) such that
\[ k_\theta e_{l,m} = e^{im\theta} e_{l,m}, \quad -l \leq m \leq l, \]
\[ X_1 e_{l,m} = \frac{i}{4} (e_{l,m+1} + e_{l,m-1}e_{l,m-1}), \]
\[ X_2 e_{l,m} = im e_{l,m}, \]
\[ X_3 e_{l,m} = \frac{1}{4} (e_{l,m+1} - e_{l,m-1}e_{l,m-1}). \]

2. The Lie algebra of the complex linear group of degree two

We need the notion of the complexification of a real vector space \( V \). By definition this is \( V_\mathbb{C} = V \times V \) as real vector space. The multiplication by \( i \) is given by
\[ i(a, b) = (-b, a). \]
This extends to an action of \( \mathbb{C} \) on \( V_\mathbb{C} \) through
\[ (\alpha + i\beta)x = \alpha x + i\beta x \quad (x \in V_\mathbb{C}) \]
and this equips $V_C$ with a structure as complex vector space. We can embed $V$ into $V_C$ by $a \mapsto (a, 0)$ and if we identify $V$ with its image than $V_C = V \oplus iV$. The following universal property holds. Let $f : V \to W$ be an $\mathbb{R}$-linear map into a complex vector space $W$. Then there exist a unique $\mathbb{C}$-linear extension $V_C \to W$. Just map $(a, b)$ to $f(a) + if(b)$.

We must give a warning. The vector space $V$ might be a complex vector space in advance. Of course we can consider $V$ as real vector space and then take its complexification. But on $V \times V$ we can also consider the complex product structure. So we have two different complex structures on the vector space $V \times V$. This might lead to confusion. To avoid this we denote the new multiplication by $i$ by

$$J(a, b) = (-b, a)$$

and the old one by

$$i(a, b) = (ia, ib).$$

2.1 Remark. Let $V$ be a complex vector space. On $V \times V$ we have two complex structures.

1) Internal multiplication with $i$ is defined through $i(a, b) = (iA, ib)$

2) External multiplication with $i$ is defined through $J(a, b) = (-b, a)$.

Obviously $iJ(a, b) = Ji(a, b)$. The complexification of $V$ is $V \times V$ together with the external $J$. We write this complex vector space as $V_C = V \times V$ (with external multiplication $J$). In simplified notation we can write

$$V_J = V + JV, \quad J(a + Jb) = -b + Ja.$$  

We apply this construction to the Lie-algebra $\mathfrak{sl}(2, \mathbb{C})$ of all complex $2 \times 2$-matrices with trace zero. We have to consider its complexification $\mathfrak{sl}(2, \mathbb{C})_C = \mathfrak{sl}(2, \mathbb{C}) \times \mathfrak{sl}(2, \mathbb{C})$. We define a Lie-bracket on $\mathfrak{sl}(2, \mathbb{C})_C$ by means of the formula

$$[A_1 + JA_2, B_1 + JB_2] := [A_1, B_1] - [A_2, B_2] + J([A_1, B_2] + [A_2, B_1]).$$

Embed $\mathfrak{sl}(2, \mathbb{C})$ into $\mathfrak{sl}(2, \mathbb{C})_C$ by $A \mapsto A + J0$. Then the Lie bracket that we introduced on $\mathfrak{sl}(2, \mathbb{C})_C$ is just the $\mathbb{C}$-linear extension of the Lie bracket on $\mathfrak{sl}(2, \mathbb{C})$. This bracket is $\mathbb{C}$-bilinear (where multiplication by $i$ is given by $J$). This means

$$[J(A_1 + JA_2), B_1 + JB_2] = J[A_1 + JA_2, B_1 + JB_2] = [A_1 + JA_2, J(B_1 + JB_2)]$$

which is easy to check. In this sense we can call $\mathfrak{sl}(2, \mathbb{C})_C$ the complexified Liealgebra of $\mathfrak{sl}(2, \mathbb{C})$ considered as real Liealgebra.

We also can consider $\mathfrak{sl}(2, \mathbb{C}) \times \mathfrak{sl}(2, \mathbb{C})$ as complex vector space (with the internal multiplication by $i$ and the Lie bracket

$$[(A_1, B_1), (A_2, B_2)] = ([A_1, B_1], [A_2, B_2]).$$

We call this the product Liealgebra. A priori this is different from $\mathfrak{sl}(2, \mathbb{C})_C$. Nevertheless we will see that both are isomorphic.
2.2 Lemma. The maps

$$\mathfrak{sl}(2, \mathbb{C}) \to \mathfrak{sl}(2, \mathbb{C})_{\mathbb{C}}, \quad A \mapsto A^\pm,$$

$$A^+ = \frac{1}{2}(A, iA), \quad A^- = \frac{1}{2}(A, -iA),$$

are $\mathbb{C}$-linear homomorphisms of Lie algebras.

Proof. The $\mathbb{C}$-linearity means of course for example $(iA)^\pm = JA^\pm$. This and the compatibility with the Lie bracket is easy to check. \qed

We simplify the notation and write for $(A, B) \in \mathfrak{sl}(2, \mathbb{C})_{\mathbb{C}}$

$$A + JB := (A, B)$$

Then we have

$$A^+ = \frac{1}{2}(\bar{A} + J\bar{A}), \quad A^- = \frac{1}{2}(A - J\bar{A}).$$

Recall that in $\mathfrak{sl}(2, \mathbb{C})$ we considered the basis $E^+, E^-, W$. (Here the signs in the exponent have nothing to do with Lemma 2.2.) We consider their images in the complexification and get 6 elements of $\mathfrak{sl}(2, \mathbb{C})_{\mathbb{C}}$

$$W^+, E^{++}, E^{+-}; \quad W^-, E^{+ -}, E^{- -}$$

which give a complex basis. Now we can prove a structure result.

2.3 Lemma. The map

$$\mathfrak{sl}(2, \mathbb{C}) \times \mathfrak{sl}(2, \mathbb{C}) \sim \to \mathfrak{sl}(2, \mathbb{C})_{\mathbb{C}}, \quad (A, B) \mapsto A^+ + B^-$$

is an isomorphism of complex Lie algebras where on the left hand side $i$ acts componentwise (and the Lie product comes from the product structure) and on the right hand side via $J$.

Proof. One has to use Lemma 2.2 and one has to check $[A^+, B^-] = 0$. \qed

The both sides in Lemma 2.3 are equal as vector spaces. But they have different structures as Lie algebras. Nevertheless they are isomorphic.

Now we consider a (complex associative) algebra $A$ and a real linear Lie algebra homomorphism

$$\varphi : \mathfrak{sl}(2, \mathbb{C}) \to A.$$

“Lie homomorphism” means that $\varphi([A, B]) = \varphi(A)\varphi(B) - \varphi(B)\varphi(A)$. We can extend it to a $\mathbb{C}$-linear Lie homomorphism

$$\varphi : \mathfrak{sl}(2, \mathbb{C})_{\mathbb{C}} \to A.$$
Here \( C \)-linear refers of course to the complexification complex structure of \( \mathfrak{sl}(2, \mathbb{C}) \) where multiplication by \( i \) is given by \( J \). This means that we have to define
\[
\varphi(A + JB) = \varphi(A) + i\varphi(B).
\]
The \( C \)-linearity means
\[
\varphi(J(A + JB)) = i\varphi(A + JB) = i(\varphi(A) + i\varphi(B)) = -\varphi(B) + i\varphi(A).
\]
Restricting \( \varphi \) to \( \mathfrak{sl}(2, \mathbb{C}) \) by means of \( A \mapsto A_+ \) or \( (A_-) \), we get two (complex linear) Lie homomorphisms
\[
\varphi_{\pm}: \mathfrak{sl}(2, \mathbb{C}) \to \mathfrak{a}.
\]
Recall that such a homomorphism produces a certain Casimir element in \( \mathfrak{a} \). It has the property that it commutes with the image of \( \mathfrak{sl}(2, \mathbb{C}) \). For trivial reason it also commutes with the image of \( \mathfrak{sl}(2, \mathbb{C})_C \). Hence we get now two Casimir elements
\[
\omega_+ = \varphi(E^{++})\varphi(E^{-+}) + 2i\varphi(W^+) - \varphi(W^+)^2,
\]
\[
\omega_- = \varphi(E^{+-})\varphi(E^{-+}) + 2i\varphi(W^-) - \varphi(W^-)^2,
\]
which commute with the image of \( \mathfrak{sl}(2, \mathbb{C})_C \) in \( \mathfrak{a} \).

2.4 Proposition. Let \( \mathfrak{sl}(2, \mathbb{C}) \to \mathfrak{a} \) be a real linear Lie homomorphism. We extend it by complex linearity to \( \mathfrak{sl}(2, \mathbb{C})_C \) and restrict it in two ways to complex linear Lie homomorphism \( \mathfrak{sl}(2, \mathbb{C}) \to \mathfrak{a} \). These Lie homomorphisms produce Casimir elements \( \omega_{\pm} \in \mathfrak{a} \). They commute with the image of \( \mathfrak{sl}(2, \mathbb{C})_C \).

3. Structure of the complex special linear group of degree two

We need a generalization of the upper half plane. The hyperbolic space is defined through
\[
\mathcal{H}_n = \mathbb{R}^{n-1} \times \mathbb{R}_{>0}.
\]
We can identify \( \mathcal{H}_2 \) with the usual upper half plane. Now we need the three dimensional hyperbolic space. We identify it with \( \mathbb{C} \times \mathbb{R}_{>0} \). We write its coordinates in the form \((z, r)\) where \( z \) is a complex number and \( r > 0 \). An elegant way to describe the action of \( \text{SL}(2, \mathbb{C}) \) on \( \mathcal{H}_3 \) is to use the skew-field of quaternions \( \mathbb{R} + i\mathbb{R} + j\mathbb{R} + k\mathbb{R} \). A quaternion is called pure if its k-component is zero. We identify the elements \((z, r) \in \mathcal{H}_3 \) with the pure quaternion \( P = z + jr \). Let \( M = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}(2, \mathbb{C}) \). On can show that the quaternion \( cP + d \) is different
from zero and define then $M(P) = (aP + b)(cP + d)^{-1}$. On also can check that $M(P)$ is in $H_3$ again and that this defines an action of $\text{SL}(2, \mathbb{C})$ from the left. We leave this as an exercise for the reader (see [EGM], 1.1). The action in the coordinates $(z, r)$ can be calculated.

We consider the distinguished point $(0, 1)$ (which corresponds to $j$). One checks that the stabilizer of this point is $\text{SU}(2)$ and one checks

$$
\begin{pmatrix}
\sqrt{r} & 0 \\
0 & \sqrt{r}^{-1}
\end{pmatrix}
\begin{pmatrix}
1 & r^{-1} z \\
0 & 1
\end{pmatrix}
(0, 1) = (z, r).
$$

In the rest of this section, we use the following notations:

$$
G = \text{SL}(2, \mathbb{C}),
$$

$$
A = \left\{ a_t = \begin{pmatrix} e^t & 0 \\ 0 & e^{-t} \end{pmatrix} ; t \in \mathbb{R} \right\},
$$

$$
N = \left\{ n_z = \begin{pmatrix} 1 & z \\ 0 & 1 \end{pmatrix} ; z \in \mathbb{C} \right\},
$$

$$
K = \text{SU}(2).
$$

Similar to the real case there is an Iwasawa decomposition.

3.1 Lemma (Iwasawa decomposition). The map

$$
A \times N \times K \longrightarrow G, \ (a, n, k) \longmapsto ank,
$$

is topological.

Proof. Let $g \in G$. We consider $g(0, 1) = (z, r)$. the we have

$$
p(0, 1) = (z, r) \quad \text{where} \quad p = \begin{pmatrix}
\sqrt{r} & 0 \\
0 & \sqrt{r}^{-1}
\end{pmatrix}
\begin{pmatrix}
1 & r^{-1} z \\
0 & 1
\end{pmatrix}.
$$

Then $k = p^{-1} g$ stabilizes $(0, 1)$ and is hence in $K$. Then $g = pk$ is the Iwasawa decomposition. 

We choose the Haar measure $dk$ of $K$ such that the volume of $K$ is one. We denote by $da$ the Haar measure on $A$. (Recall that it is $da/a$. We hope that there arises no confusion from the fact that we frequently denote by $a$ an element of $\mathbb{R}_{>0}$ and also the diagonal matrix with entries $a, a^{-1}$.) and we denote by $dz = dx dy$ the usual Lebesgue measure on $\mathbb{C}$.

3.2 Proposition. A Haar measure on $G = \text{SL}(2, \mathbb{C})$ can be obtained as

$$
\int_G f(x) dx = \int_A \int_N \int_K f(ank) dk \, dn \, da.
$$
4. Casimir operator for the complex special linear group of degree two

We have to start with a real Lie homomorphism
\[ \varphi : \mathfrak{sl}(2, \mathbb{C}) \longrightarrow A \]
where \( A \) is a complex associative algebra. First we have to extend \( \varphi \) to a \( \mathbb{C} \)-linear map
\[ \varphi : \mathfrak{sl}(2, \mathbb{C}) \longrightarrow A. \]
To extend \( \varphi \) in the \( \mathbb{C} \)-linear way we have to define
\[ \varphi(A + JB) = \varphi(A) + i \varphi(B). \]
Now we make use of the two embeddings
\[ \mathfrak{sl}(2, \mathbb{C}) \longrightarrow \mathfrak{sl}(2, \mathbb{C})_{\mathbb{C}}, \quad A \mapsto A^\pm. \]
They induce the two \( \mathbb{C} \)-linear homomorphisms
\[ \varphi^\pm : \mathfrak{sl}(2, \mathbb{C}) \rightarrow A, \quad \varphi^+(A) = \frac{1}{2} (\varphi(\bar{A}) + i \varphi(iA)), \]
\[ \varphi^-(A) = \frac{1}{2} (\varphi(A) - i \varphi(iA)). \]
The point is that these are \( \mathbb{C} \)-linear (but \( \varphi \) needs not). Hence each of the both gives a Casimir operator.

We consider a special \( \varphi \),
\[ \varphi : \mathfrak{sl}(2, \mathbb{C}) \longrightarrow \text{End}(C^\infty(G)) \]
that is defined through the Lie derivative.
\[ (\varphi(A)(f)) = \frac{d}{dt} f(x \exp(tA)) \big|_{t=0}. \]
This map is only real linear (but \( C^\infty(G) \) means the space of complex valued functions. Even more general, one can consider differentiable functions on \( G \) with values in a complex Banach space). We use the notations
\[ A = \varphi(A) \]
and sometimes we write simply
\[ Af = A f \]
if the context clearly indicates what is meant. In the case of the group \( SL(2, \mathbb{R}) \) we got explicit formulas for a concrete basis of the Lie algebra. The case \( SL(2, \mathbb{C}) \) is more involved. We must be satisfied with a weaker result. For this we consider a finite dimensional unitary representation \( \sigma : K \to GL(H) \) of the compact group \( K = SU(2) \). Then we consider differentiable functions

\[
f : SL(2, \mathbb{C}) \to H, \quad f(xk) = \sigma(k)f(x) \quad (x \in SL(2, \mathbb{C}), \, k \in K).
\]

Such a function is determined by its restriction \( f_0 \) to \( AN \), since

\[
f(ank) = \sigma(k)f_0(an)
\]

and each differentiable function \( f_0 \) on \( AN \) extends to a function \( f \).

We consider now a Casimir operator \( C \). Since \( C \) is right invariant, we get the following result.

\[\text{Lemma.} \quad \text{Let \( C \) be a Casimir operator for \( G = SL(2, \mathbb{C}) \) and \( f : G \to H \) be a differentiable function with the transformation property \( f(xk) = \sigma(k)f(x) \). Then \( g = C(f) \) has the same transformation property.}\]

Hence there exists an operator

\[
C_0 : \mathcal{C}^\infty(AN) \to \mathcal{C}^\infty(AN)
\]

such that \( Cf = g \) means \( C_0f_0 = g_0 \).

We apply this to the operators \( \omega_\pm \) instead of \( C \). The corresponding operators \( C_0 \) are denoted by \( \Delta_\pm \). They depend on \( \sigma \). We will compute them explicitly.

### 5. Differentiable vectors

As in the case of \( SL(2, \mathbb{R}) \) we can define the notion of analytic functions (may be Banach space valued) on \( G \). Just use the Iwasawa coordinates. It is clear that \( G \) acts on the space of differentiable or analytic vectors by translation (from left or right). We consider irreducible unitary representations \( \pi : G \to GL(H) \). A vector \( h \in H \) is called differentiable (analytic) if the function \( \pi(x)h \) is differentiable (analytic). We denote by \( H^\infty \) the subspace of differentiable vectors and by \( H^\omega \) the subspace of analytic vectors and we denote by \( H_K \) the space of the \( K \)-finite vectors. Recall that this is the algebraic sum of all (finite dimensional) subspaces which are invariant under \( K \). The spaces of differentiable (analytic) elements are invariant under the action of \( G \). As in the case \( SL(2, \mathbb{R}) \) it is easy to prove that the space of differentiable functions is dense. In the case \( SL(2, \mathbb{R}) \) we proved more. Again we need more, namely
§6. Multiplicity one

that the space of analytic functions is dense. To prove this, it is sufficient to show
\[ H_K \subset H^\omega \quad (\subset H^\infty \subset H). \]
This is more involved than in the case SL(2, ℝ) and needs several preparations.

We consider the restriction of \( K \) and decompose the representation into isotypics with respect to \( K \).

\[ H = \bigoplus_{\sigma \in \hat{K}} H(\sigma). \]

Then \( H_K \) is the algebraic sum of the \( H(\sigma) \).

5.1 Lemma. Let \( \pi : G \to \text{GL}(H) \) be a unitary representation. The space of differentiable elements in \( H(\sigma) \) is dense in \( H(\sigma) \).

Proof. As in the case of SL(2, ℝ) we know that the elements
\[ \pi(f)h = \int_G f(x)\pi(x)dx, \quad f \in C_c^\infty(G), \]
are differentiable. They generate a dense subspace of \( H \). Hence their orthogonal projection to \( H(\sigma) \) generates a dense subspace of \( H(\sigma) \). It remains to show that the projections are differentiable. This follows from the Peter Weyl theorem.

\[ \square \]

6. Multiplicity one

In this section we generalize the multiplicity one theorem (Theorem II.6.7) to \( G = \text{SL}(2, \mathbb{C}), K = \text{SU}(2) \).

6.1 Theorem. Let \( \pi : G \to \text{GL}(H) \) be an irreducible unitary representation. In the restriction of \( \pi \) to \( K \) each irreducible representation of \( K \) occurs with multiplicity \( \leq 1 \).

Proof. The proof is different from the proof in the SL(2, ℝ). There we made use of the commutativity of the algebra \( S_{n,n} \) which now is not available.

We explain the analogue of \( S_{n,n} \). For this we need a generalization of the convolution product. Let \( G \) be a locally compact unimodular group and let \( K \subset G \) be a compact subgroup and let \( dx, dk \) be their Haar measures. Then we have convolution products \( \alpha * \beta \) on \( \mathcal{C}(K) \) and \( f * g \) on \( \mathcal{C}_c(G) \) and, in addition
\[ \mathcal{C}_c(G) \times \mathcal{C}_c(G) \to \mathcal{C}_c(G), \quad (\alpha * f)(x) = \int_K \alpha(k)f(k^{-1}x)dk, \]
\[ \mathcal{C}_c(G) \times \mathcal{C}(K) \to \mathcal{C}_c(G), \quad (f * \alpha)(x) = \int_K f(xk)\alpha(k^{-1})dk. \]
Notice that in the case $G = K$ this is the usual convolution product. The associative law remains valid, for example $f * (\alpha * \beta) = (f * \alpha) * \beta$.

Now we consider a unitary representation $\pi : G \to \text{Un}(H)$. We want to study its restriction to $K$. Therefore we consider some $\sigma \in \hat{K}$. We recall the element $e_\sigma$ that is an idempotent in the convolution algebra $C(K)$. For any $f \in C_c(G)$ we consider $e_\sigma * f * e_\sigma$. From the Peter Weyl theorem follows that $\pi(e_\sigma * f * e_\sigma)$ maps $H(\sigma)$ into itself. Therefore it looks natural to consider

$$C_{c,\sigma}(G) = \{ e_\sigma * f * e_\sigma; \ f \in C_c(G) \}.$$

### 6.2 Theorem

Let $G$ be a locally compact group and let $K \subset G$ be a compact subgroup. Let $\sigma \in \hat{K}$. Then $C_{c,\sigma}(G)$ is a star algebra (sub algebra of $C_c(G)$). Let $\pi : G \to \text{Un}(H)$ be a unitary representation. Then $C_{c,\sigma}(G)$ acts on the isotypic component $H(\sigma)$.

In the following we need the von-Neumann density theorem. It is explained in Sect. 3 from the Appendices (Chap. VI). It uses the SOT-topology on $B(H)$ where $H$ is a Hilbert space. We have to use Theorem VI.3.3. Let $\pi$ be irreducible. Then the image of $C_c(G)$ in $B(H)$ is SOT-dense. An easy consequence is that the image of $C_{c,\sigma}$ is SOT-dense in $B(H(\sigma))$.

### 6.3 Definition

An associative algebra $A$ admits many finite dimensional representations, bounded by $n$, if for every $A \in A$, $A \neq 0$, there exists a homomorphism $\pi : A \to \text{End}(H)$, $\dim(H) \leq n$, $\pi(A) \neq 0$.

### 6.4 Theorem (Kaplansky-Godement)

Let $A$ be an associative algebra that admits many finite dimensional representations, bounded by $n$. Let $H$ be a Hilbert space and $A \to B(H)$ a homomorphism such that the image of $A$ is SOT-dense, then $\dim(H) \leq n$.

We apply the theorem of Kaplansky-Godement to $A = C_c,\sigma$ and to $H = H(\sigma)$. We make use of a result which we will formulate and prove a little later. It concerns the construction of the principal series of $\text{SL}(2, \mathbb{C})$. The corresponding representation of $C_{c,\sigma}$ will turn out to be isomorphic to $\sigma$. This means that $A$ admits many finite dimensional representations, bounded by $\dim(H(\sigma))$. So we obtain that $H(\sigma)$ is irreducible. This completes the proof of Theorem 6.1.

### 7. Admissibility

In the case $G = \text{SL}(2, \mathbb{R})$, $K = \text{SO}(2)$ we considered admissible $g$-$K$-modules. This concept works also in the case $G = \text{SL}(2, \mathbb{C})$, $K = \text{SU}(2)$ (and even in more generality). We keep short.
Let $\pi : G \to \text{Un}(H)$ be a unitary representation of $G = \text{SL}(2, \mathbb{C})$. We decompose $H$ into isotypic components $H(\sigma), \sigma \in \hat{K}$. Their algebraic sum $H_K$ consists of all $K$-finite vectors. They are differentiable and the formula

$$ \pi(k) \circ d\pi(A) = d\pi(kAk^{-1}) \circ d\pi(A), \quad k \in K, \ A \in g, $$

holds. Here $g = \mathfrak{sl}(2, \mathbb{C})$ considered as real Lie algebra. This formula shows that $g$ acts on $H_K$. So we are lead to the notion of a $g$-$K$-module ($K = \text{SU}(2)$).

This is a complex vector space $\mathcal{H}$ together with an action of $K$ (homomorphism $\pi : K \to \text{GL}(\mathcal{H})$) and an action of $g$ ($\mathbb{R}$-linear) Lie-homomorphism $d\pi : g \to \text{End}(\mathcal{H})$ such that the above compatibility relation is true and such that all elements of $\mathcal{H}$ are $K$-finite.

Since the Lie-homomorphism $d\pi : g \to \text{End}(\mathcal{H})$ it is not determined through the restriction to $\mathfrak{sl}(2, \mathbb{R})$ or $\mathfrak{su}(2)$. But we can extend it to a $\mathbb{C}$-linear Lie homomorphism $g_{\mathbb{C}} \to \text{End}(\mathcal{H})$.

Such a $g$-$K$-module is called admissible of the isotypic components $H(\sigma), \sigma \in \hat{K}$ are finite dimensional and irreducible admissible if, in addition if for each $h \in H(\sigma), h \neq 0$, one has $A(h) = \mathcal{H}$. Here $A$ is the $\mathbb{C}$-algebra generated by the image of $g$.

7.1 Remark. Let $\mathcal{H}$ be an irreducible admissible $g$-$K$-module ($g = \mathfrak{sl}(2, \mathbb{C}), K = \text{SU}(2)$). Then the Casimir operators act by scalars on $\mathcal{H}$.

So we have seen that, as in the case $\text{SL}(2, \mathbb{R})$, every unitary irreducible representation of $G = \text{SL}(2, \mathbb{C})$ on a Hilbert space $H$ induces a structure as irreducible admissible $g$-$K$-module on $\mathcal{H} = H_K$. It should be clear what it means that two $g$-$K$ modules are isomorphic. Then we have, as in the case $\text{SL}(2, \mathbb{R})$.

Two irreducible unitary representations of $G = \text{SL}(2, \mathbb{C})$ are isomorphic if and only of the assicated $g$-$K$-modules are isomorphic.

Now we have the following two tasks.

1) Classify all irreducible admissible $g$-$K$-modules.

2) Exhibit those which come from an irreducible unitary representation of $G = \text{SL}(2, \mathbb{C})$.

In the case $\text{SL}(2, \mathbb{R})$ we solved both problems. Now we are content with a slightly weaker argument.

A $g$-$K$-module is called unitarizable if there exists a (Hermitian positive definit) scalar product on $\mathcal{H}$ such that the elements $A \in g$ act skew symmetric, $\langle Ax, y \rangle = -\langle x, Ay \rangle$ and if the operators $\pi(k)$ are unitary.

As in the $\text{SL}(2, \mathbb{R})$ it is rather clear that the $g$-$K$-module associated to an irreducible unitary representation of $G = \text{SL}(2, \mathbb{C})$ is unitarizable.

We have to classify unitarizable irreducible admissible $g$-$K$-modules.
8. Unitary dual of the complex special linear group of degree two

Let \( \pi : G \to \text{Un}(H) \) be an irreducible and unitary representation of \( G = \text{GL}(2, \mathbb{C}) \). We restrict it to \( K = \text{SU}(2) \). We know that the isotypic components \( H(\sigma) \) for \( \sigma \in \hat{K} \) are finite dimensional.

We also know that space of differentiable vectors in \( H(\sigma) \) is dense. Hence all vectors of \( H(\sigma) \) are differentiable. Hence we can apply the Casimir operator \( C \).

8.1 Theorem. Let \( \pi : G \to \text{GL}(H) \) be a unitary representation. The \( K \)-finite elements \( h \in H_K \) are analytic.

Proof. We denote by \( \mathcal{H} = H_K \) the algebraic sum of the \( K \)-irreducible subspaces of \( H \). It can be shown that they consist of differentiable (even analytic) vectors such that the derived representation

\[
d\pi : g \to \text{End}(\mathcal{H})
\]

can be defined through the same formula as in the \( \text{SL}(2, \mathbb{R}) \)-case. Notice that this is an \( \mathbb{R} \)-linear Lie homomorphism. The complex structure of \( \mathfrak{sl}(2, \mathbb{C}) \) plays no role here. Here we have to consider \( \mathfrak{sl}(2, \mathbb{C}) \) as real Lie algebra. Of course we can extend this representation \( \mathbb{C} \)-linearly to the complexification

\[
\mathfrak{sl}(2, \mathbb{C})_{\mathbb{C}} = \mathfrak{sl}(2, \mathbb{C}) + J\mathfrak{sl}(2, \mathbb{C}).
\]

Then we can consider the Casimir operators \( \omega^\pm \in \text{End}(\mathcal{H}) \). Similar to the \( \text{SL}(2, \mathbb{R}) \)-case it can be shown that both act by multiplication with constants \( \mu^\pm \). These are basic invariants of the representations. We can define an other invariant \( l_0 \in \{0, 1/2, 1, \ldots \} \). It is the smallest \( l \) such that the representation \( \varrho : K \to \text{GL}(V_l) \) occurs in \( \pi|K \).

8.2 Theorem. A unitarizable irreducible admissible \( \mathfrak{sl}(2, \mathbb{C}) \)-\( \text{SU}(2) \)-module is determined by the parameters \( l_0, \mu^+, \mu^- \) up to unitary isomorphism. The parameters \( \mu^\pm \) are real and satisfy the relations

\[
\mu_2^2 = 32l_0^2(\mu_1 + 8l_0^2 - 8), \quad 32(l_0 + 1)^2(\mu_1 + 8l_0^2 + 16l) - \mu_2^2 > 0.
\]

Proof. We have a decomposition

\[
\mathcal{H} = \bigoplus_{\text{certain } l} \mathcal{H}(l)
\]
where $\mathcal{H}(l)$ is invariant and irreducible under $\text{SU}(2)$ of dimension $2l + 1$. As in Proposition II.12.12 we use a basis of $H(l)$

$$e_{l,-l}, e_{l,-l+1}, \ldots, e_{l,-1}, e_{l,l}$$

and we set

$$\mathcal{H}(l,m) = C e_{l,m}.$$ 

So we have

$$\mathcal{H} = \bigoplus_{-l \leq m \leq l} \mathcal{H}(l,m).$$

The bases have the following properties.

$$X_1 e_{lm} = \frac{i}{4} (e_{l,m+1} + e_{l,m-1} e_{l,m-1}),$$

$$X_2 e_{lm} = i m e_{l,m},$$

$$X_3 e_{lm} = \frac{1}{4} (e_{l,m+1} - e_{l,m-1} e_{l,m-1}).$$

We choose an explicit $\mathbb{R}$ basis of $\mathfrak{sl}(2, \mathbb{C})$,

$$X_1, X_2, X_3, iX_1, iX_2, iX_3.$$ 

We know how the elements $X_1, X_2, X_3$ act on $\mathcal{H}$. But we do not know so far how $iX_1, iX_2, iX_3$ act. Recall the module structure of $\mathcal{H}$ is given through real linear Lie homomorphism

$$\varphi : \mathfrak{sl}(2, \mathbb{C}) \rightarrow \text{End}(\mathcal{H}).$$

This has been extended $\mathbb{C}$-linear to $\mathfrak{sl}(2, \mathbb{C})_\mathbb{C}$. This means $\varphi(JA) = i \varphi(A)$. But $\varphi(iA)$ and $i \varphi(A)$ are different.

The basis $X_1, \ldots, iX_3$ is also a $\mathbb{C}$-basis of the complexification $\mathfrak{sl}(2, \mathbb{C})_\mathbb{C}$. Since the extension of $\text{det}$ to this complexification is $\mathbb{C}$-linear, it seems to be natural to work in the complexification with a $\mathbb{C}$-basis. There is another natural $\mathbb{C}$-basis of $\mathfrak{sl}(2, \mathbb{C})_\mathbb{C}$. For this we recall the two $\mathbb{C}$-linear embeddings

$$\mathfrak{sl}(2, \mathbb{C}) \rightarrow \mathfrak{sl}(2, \mathbb{C})_\mathbb{C}, \quad A \mapsto A^\pm,$$

$$A^+ = \frac{1}{2} (\hat{A} + J(\hat{i}A)), \quad A^- = \frac{1}{2} (\hat{A} - J(\hat{i}A)).$$

We choose in $\mathfrak{sl}(2, \mathbb{C})$ the elements $W, E^+, E^-$ and take there images under $A \mapsto A^\pm$.

$$W^+, E^{++}, E^{-+}; \quad W^-, E^{+-}, E^{--}.$$ 

This is also a $\mathbb{C}$-basis of the complexification.
We have
\[
E^{++} = \frac{1 + J_i}{2} E^-,
E^{+-} = \frac{1 - J_i}{2} E^+,
E^{--} = \frac{1 + J_i}{2} E^-,
E^{-+} = \frac{1 - J_i}{2} E^+,
W^+ = \frac{1 + J_i}{2} W,
W^- = \frac{1 - J_i}{2} W.
\]

Making use of \(W = 2X_2\) and \(E^\pm = 2(\pm X_3 - iX_1)\) we obtain
\[
E^{++} = -(1 + J_i)(X_3 + iX_1),
E^{+-} = (1 + J_i)(X_3 - iX_1),
W^+ = (1 + J_i)X_2,
E^{-+} = (1 - J_i)(X_3 - iX_1),
E^{--} = -(1 - J_i)(X_3 + iX_1),
W^- = (1 - J_i)X_2.
\]

We apply \(\varphi\) which is \(\mathbb{C}\)-linear with respect to \(J\) (but not to \(i\) and obtain
\[
\varphi^+(E^+) = -\varphi(X_3 + iX_1) + i\varphi(X_1 - iX_3),
\varphi^+(E^-) = \varphi(X_3 - iX_1) + i\varphi(X_1 + iX_3),
\varphi^+(W) = \varphi(X_2) + i\varphi(iX_2),
\varphi^-(E^+) = \varphi(X_3 - iX_1) - i\varphi(X_1 + iX_3),
\varphi^-(E^-) = -\varphi(X_3 + iX_1) + i\varphi(-X_1 + iX_3),
\varphi^-(W) = \varphi(X_2) - i\varphi(iX_2).
\]

For the Casimir operators we get
\[
\omega_- = \varphi^+(E^+)\varphi^+(E^-) + 2i\varphi^+(W) - (\varphi^+(W))^2,
\omega_- = -(\varphi(X_1)^2 + \varphi(X_2)^2 + \varphi(X_3)^2)
+ \varphi(X_1)^2 + \varphi(X_2)^2 + \varphi(X_3)^2
- 2i(\varphi(X_1)\varphi(X_1)^2 + \varphi(X_2)\varphi(X_2) + \varphi(X_3)\varphi(X_3))
- \varphi^-(E^+)\varphi^-(E^-) + 2i\varphi^-(W) - (\varphi^-(W))^2,
\omega_- = -(\varphi(X_1)^2 + \varphi(X_2)^2 + \varphi(X_3)^2)
+ \varphi(X_1)^2 + \varphi(X_2)^2 + \varphi(X_3)^2
+ 2i(\varphi(X_1)\varphi(X_1)^2 + \varphi(X_2)\varphi(X_2) + \varphi(X_3)\varphi(X_3))
\]
8. Unitary dual of the complex special linear group of degree two

Instead of $\omega_+, \omega_-$ we will use also

$$\Box_+ = -\frac{\omega_+ + \omega_-}{2}, \quad \Box_- = i\frac{\omega_+ - \omega_-}{4}. $$

\[
\begin{align*}
\Box_+ &= \varphi(X_1)^2 + \varphi(X_2)^2 + \varphi(X_3)^2 - \varphi(iX_1)^2 - \varphi(iX_2)^2 - \varphi(iX_3)^2 \\
\Box_- &= \varphi(X_1)\varphi(iX_1) + \varphi(X_2)\varphi(iX_2) + \varphi(X_3)\varphi(iX_3)
\end{align*}
\]

We introduce a new basis.

$$W = 2X_2, \quad R^+ = 2(X_3 - JX_1), \quad R^- = 2(-X_3 - JX_1)$$

Its advantage is that $R^\pm$ are lowering resp. raising operators

$$We_{m} = 2im\epsilon_{l,m}, \quad R^+\epsilon_{l,m} = \epsilon_{l,m+1}, \quad R^-\epsilon_{l,m} = \epsilon_{l,m-1}. $$

The generated complex sub-vector space of $\mathfrak{sl}(2, \mathbb{C})$ (complex structure coming from $J$) is

$$\mathfrak{u}(2) + J\mathfrak{u}(2).$$

This is isomorphic to $\text{SL}(2, \mathbb{C})$ (complex structure coming from $i$). The isomorphism comes from the correspondence

$$W \leftrightarrow W, \quad E^+ \leftrightarrow R^+, \quad E^- \leftrightarrow R^-. $$

We consider also the elements

$$W' = iW, \quad R'^+ = iR^+, \quad R'^- = iR^-.$$

Then the 6 elements

$$W, R_+, R_-, \quad W', R'_+, R'_-$$

give a complex basis (complex structure coming from $J$) of $\mathfrak{sl}(2, \mathbb{C})$. The relations between them can be computed. The result is

$$\begin{align*}
[R^+, R'^+] &= 0 & [R^+, R'^-] &= -4JW' & [R^+, W'] &= -2JR'^+ \\
[R^-, R'^+] &= 4JW' & [R^-, R'^-] &= 0 & [R^-, W'] &= +2JR'^-
\end{align*}$$

The first row of this table corresponds to the known relations between $W, E^+, E^-$. The second row is a trivial consequence of the first row. The rest can be verified directly.
We want to work out the action of \( W', R_+', R_- \) on \( \mathcal{H} \). Recall that

\[
\mathcal{H} = \bigoplus_{certain\ l \leq m \leq l} \mathcal{H}(l, m)
\]

where the occurring \( \mathcal{H}(l, m) = \mathbb{C} e_{l, m} \) are one dimensional. We know already the action of \( W, R_+, R_- \). The basis elements \( e_{l, m} \) can be taken such that

\[
\begin{align*}
W : \mathcal{H}(l, m) &\sim \rightarrow \mathcal{H}(l, m), \quad We_{l, m} = 2im e_{l, m}, \\
R_+ : \mathcal{H}(l, m) &\sim \rightarrow \mathcal{H}(l, m + 1), \quad R_+ e_{l, m} = e_{l, m+1} \quad (-l \leq m < l), \\
R_- : \mathcal{H}(l, m + 1) &\sim \rightarrow \mathcal{H}(l, m), \quad R_- e_{l, m+1} = c_{l, m} e_{l, m} \quad (-l \leq m < l)
\end{align*}
\]

with known constants \( c_{l, m} \). We notice that we can change for each \( l \) the basis element \( e_{l, m} \) by a constant depending on \( l \).

We introduce the operator

\[
\mathcal{K} = R_+ R_- - 2JW + W^2 = R_- R_+ + 2JW + W^2.
\]

Recall that we have a Lie homomorphism \( \mathfrak{sl}(2, \mathbb{C}) \rightarrow \text{End}(\mathcal{H}) \) which is \( \mathbb{C} \)-linear with respect to the complex structure on \( \mathfrak{sl}(2, \mathbb{C}) \) defined through \( J \).

The element \( \mathcal{K} \) can be considered as element of \( \text{End}(\mathcal{H}) \). It commutes with the image of \( \mathfrak{su}(2) + J\mathfrak{su}(2) \). Recall that this is isomorphic to \( \text{SL}(2, \mathbb{C}) \) and \( \mathcal{K} \) corresponds to the Casimir operator \( E^+ E^- - 2W + W^2 \). But \( \mathcal{K} \) doesn’t commute with the image of \( \mathfrak{sl}(2, \mathbb{C}) \). Since the group \( \text{SU}(2) \) acts irreducibly on \( \mathcal{H}_l \), the operator \( \mathcal{K} \) acts through a scalar on \( \mathcal{H}_l \).

**8.3 Lemma.** The operator \( \mathcal{K} \) acts on \( \mathcal{H}(l) \) through multiplication with the scalar \(-4l(l + 1)\).

**Proof.** The easiest way to get this scalar is to compute it on \( \mathcal{H}_{l,l} \), since \( R_+ \) annihilates this space. The result is

\[
\mathcal{K} : \mathcal{H}(l) \sim \rightarrow \mathcal{H}(l), \quad \mathcal{K} e_{l,m} = -4l(l + 1) e_{l,m}. \quad \Box
\]

We have to determine the action of \( W', R_+', R_- \) on \( \mathcal{H} \). For this we have to use the commutator relations between them and \( W, R_+, R_- \).

Our next goal is to determine the action of \( R_+ \) on \( \mathcal{H}(l, l) \). We know that this space is in the kernel of \( R_+ \). (The kernel of \( R^+ \) is the sum of all \( \mathcal{H}(l, l) \) theta occur in \( \mathcal{H} \). Since \( R^+ \) and \( R_+ \) commute, the element \( R^+(v) \) for every \( v \in \mathcal{H}(l, l) \) is contained in the kernel of \( R^+ \). Hence it is contained in the sum \( \sum \mathcal{H}(v, v) \). Now we make use of the commutation rule \([W, R^+] = 2JR^+\). It implies

\[
W(R^+) = 2i(l + 1)R^+ v.
\]

A similar argument works for \( R_- \). So we get the following result.
§8. Unitary dual of the complex special linear group of degree two

8.4 Lemma. We have

\[ R'^+: \mathcal{H}(l, l) \to \mathcal{H}(l + 1, l + 1), \]
\[ R'^- : \mathcal{H}(l, -l) \to \mathcal{H}(l + 1, -l - 1). \]

Next we want to compute the action of \( W' \) on \( \mathcal{H}(l, l) \). This is more involved. We have to bring the two Casimir operators \( \square \pm \) into the game. A straightforward computation shows

\[ \square_+ = 2(\varphi(W)^2 - \varphi(W')^2) - 8i\varphi(W) + 2\varphi(R'^+)\varphi(R'^-) + 2\varphi(R'^+)\varphi(R'^-), \]
\[ \square_- = 4\varphi(W)\varphi(W') - 8i\varphi(W') + 2i\varphi(R^-)\varphi(R'^+) + 2i\varphi(R'^-)\varphi(R'^+). \]

We will use also the simplified notation

\[ \square_+ = 2(W^2 - W'^2) - 8iW + 2R'^+ R'^- + 2R'^+ R'^-, \]
\[ \square_- = 4WW' - 8iW' + 2iR^- R'^+ + 2iR'^- R'^+. \]

We know that these operators act by a scalar on \( \mathcal{H} \),

\[ \square^+ a = \mu^+ a, \quad \square^- a = \mu^- a. \]

We apply the second equation to \( a \in \mathcal{H}(l, l) \). Since \( a \) is annihilated by \( R'^+ \), we get commute we get

\[ (4WW' - 8iW'^+ 2iR^- R'^+) a = \mu^- a. \]

Since \( W \) and \( W' \) commute we get

\[ (4WW' - 8W') a = 8(l - 1)W'a. \]

This gives the following result.

8.5 Lemma. We have

\[ W' : \mathcal{H}(l, l) \to \mathcal{H}(l, l) \oplus \mathcal{H}(l + 1, l). \]

Next we want to determine the action of \( W' \) on \( \mathcal{H}(l, l - 1) \). For this we use the relation

\[ [R'^+, [R'^-, W']] = 8W' \]

which follows from the table of relations above.
8.6 Lemma. Let $H(l,l)$ be non zero. Then $R'$ is non zero on $H(l,l)$.

**Corollary.** Let $l_0$ be the smallest $l_0$ such that $H(l_0,l_0)$ is non zero. Then $H(l,l)$ is non zero for all $l \geq l_0$.

**Proof.** We have to show that $\sum_{l \geq l_0} H(l)$ is invariant under $\mathfrak{sl}(2,\mathbb{C})$ or which means the same, under $\mathfrak{sl}(2,\mathbb{C})_C$.

The point is now that in the cases which are described in the theorem, all parameters under the described constraints can be actually realized by an irreducible unitary representation of $g$. Similar to the $\text{SL}(2,\mathbb{R})$-case, it is better to introduce a new parameter $s$ be the definition

$$s^2 = (\mu_1 + 8l^2 - 8)/8.$$  

This means

$$\mu_1 = 8(s^2 + 1 - l^2), \quad \mu_2 = (16ls)^2.$$  

In the case $l \neq 0$ we can fix $s$ such that

$$\mu_2 = 16ls \quad (l \neq 0).$$

In the case $s = 0$ this makes no sense. So in this case we have to be satisfied with the fact that $s$ is only determined up to sign.

Now we have to check for which $s$ the inequality in Theorem 8.2 is satisfied. Obviously it is satisfied if $s$ is a real number. We call the triples $l, \mu^+, \mu^-$ which came from real $s$ the principal series. But that ist all. In the case $l = 0$ one This parameter is defined up to the sign. With this parameter we can also take $s = it$ where $t \in (-1,1)$. This is called the complementary series.

8.7 Theorem. **Principal Series.**

For every $l \in \{0,1/2,1,\ldots\}$ and for any real $s$ there exists an irreducible unitary representation $\pi_{l,s}$ which produces the parameters $(l,\mu^+,\mu^-)$ where

$$\mu_1 = 8(s^2 + 1 - l^2), \quad \mu_2 = 16ls.$$  

The parameter $s$ is uniquely determined if $l \neq 0$ and up to the sign if $l = 0$.

**Complementary Series.**

The same statement is true for $l = 0$ and $s = it$, $t \in (-1,1)$. Here $s$ is also determined.

Every unitary irreducible representation of $\text{GL}(2,\mathbb{C})$ is unitary isomorphic to a representation of these two lists.

In the following we will describe the realization of the principal series.
Chapter IV. Mackey’s theory of the induced representation

1. Induced representations, simple case

The basic idea of induced representations is easy to explain. Let \( P \subset G \) be a subgroup of a finite group and \( \sigma : P \to \text{GL}(H) \) a representation of the subgroup. We consider the space \( \text{Ind}(\sigma) \) of all functions \( f : G \to H \) with the property
\[
f(px) = \sigma(p)f(x) \quad \text{for} \quad p \in P, \ x \in G.
\]
Then \( G \) acts by right translation on \( \text{Ind}(\sigma) \). Assume that \( G \) is a locally compact group and that \( P \) is a closed subgroup. We want to modify this construction in such a way that we get – for certain \( \sigma \) – a unitary induced representation. An example was already given by the construction of the principal series in Chap. I, Sect. 7. Here \( G = \text{SL}(2, \mathbb{R}) \) and \( P \) is the subgroup of all upper triangular matrices with positive diagonal, \( \sigma \) was the one dimensional unitary representation given by the character \( \sigma(p) = a^{1+s} \) where \( \text{Re} \ s = 0 \).

Already in this case we had to deal with the problem is that the condition \( \Delta_G|_P = \Delta_P \) may be false so there is no \( G \)-invariant measure on \( P \setminus G \).

Before we go to the general case we make a very restrictive assumption which was satisfied in the example of the principal series. We assume that there exists a closed subgroup \( K \subset G \) be a closed subgroup of the locally compact group \( G \) such that the multiplication map \( P \times K \to G \) is a topological map. We assume that \( G \) and \( K \) are unimodular but we do not assume that \( P \) is unimodular. Let \( \Delta \) be the modular function of \( P \).

1.1 Lemma. Let \( y \in G \). We consider the (continuous) maps \( \alpha : K \to K \) and \( \beta : K \to P \) which are defined by \( ky = \beta(k)\alpha(k) \). Then for each \( f \in C_c(K) \) the formula
\[
\int_K f(\alpha(k))\Delta(\beta(k))dk = \int_K f(k)dk
\]
holds.

Proof. This is a generalization of Lemma II.3.1. The same proof works.

Now we can give a straightforward generalization of the principal series. Let \( \sigma : P \to \text{GL}(H) \) be a unitary representation of \( P \). We consider functions
IndRep 1.2 Proposition. We assume that \( G = PK \) and that \( G \) and \( K \) are both unimodular. Let \( \sigma : P \to \text{GL}(V) \) be a unitary representation. The group \( G \) acts on functions \( f : G \to V \) with the transformation property
\[
f(py) = \Delta(p)^{1/2} \sigma(p)f(y), \quad p \in P, \ y \in G.
\]
(it is essential that we do not induce \( \sigma \) directly but modify it with the factor \( \Delta(p)^{1/2} \).) Such a function is determined by its restriction to \( K \) and every function on \( K \) can be extended to a function with this transformation property on \( G \). The group \( G \) acts by translation from the right on the space of functions with this transformation property. We can this consider as an action of \( G \) on the space of all functions \( f : K \to V \).

2. Induced representations, the general case

Unfortunately this construction which we gave in Sect. 2 is not good enough. We want to give up the existence of a decomposition \( G = KP \). We simply assume that \( P \subset G \) is a closed subgroup of a locally compact group.

The following procedure to overcome this difficulty is due to Mackey. Since we have do differ between left- and right-invariant measures, we will denote by \( d_l x \) a left invariant measure on \( G \) and by \( d_r p \) a right invariant measure on \( P \).

AssuC 2.1 Assumption. There exists a function \( q : G \to \mathbb{R}_{>0} \) which is measurable for any Radon measure on \( G \) such that \( q \) and \( q^{-1} \) are locally bounded and with the property
\[
q(px) = \frac{\Delta_P(p)}{\Delta_G(p)} q(x).
\]

There is an important case where the existence of a function \( q \) is trivial.
2.2 Remark. Let $P, K \subset G$ we closed subgroups of a locally compact group such that the map

$$P \times K \xmapsto[]{\sim} G, \quad (p, k) \mapsto pk,$$

is topological. Then the function

$$q(pk) = \frac{\Delta_P(p)}{\Delta_G(p)}$$

satisfies the Assumption 2.1.

In this case the function $q$ is continuous. The essential point that the Assumption 2.1 is satisfied in much more general situations (with functions $q$ which may be nor continuous).

Let us assume for example the following:

There exists an open non-empty subset $U \subset P \setminus G$ and a continuous section $s : U \to G$.

(Section means that $s(a)$ is a representative of the coset $a \in P \setminus G$.) Let $\bar{U}$ be the inverse image of $U$ in $G$ and $\pi : \bar{U} \to U$ the natural projection. We can consider the continuous function

$$q_U : \bar{U} \to \mathbb{R}_{>0}, \quad q_U(x) = \frac{\Delta_P(xs(\pi(x))^{-1})}{\Delta_G(xs(\pi(x))^{-1})}.$$

Then $q_U$ has the desired transformation on $\bar{U}$. Taking translates we can cover $P \setminus G$ with sets $U$. Since we have countable basis of the topology we can write

$$P \setminus G = U_1 \cup U_2 \cup \cdots$$

such that in each inverse image $\bar{U}_i$ a function $q_i = q_{U_i}$ with such a property exist. We want to glue the $q_i$ and do this in the most simple way. We consider the disjoint decomposition

$$P \setminus G = B_1 \cup B_2 \cup \cdots \quad \text{where} \quad B_n = U_n - (U_1 \cup \cdots \cup U_{n-1}).$$

We now define $q$ such that its restriction to $B_i$ is $q_i$. This is a measurable function for any Radon measure, since the sets $B_i$ are measurable sets. (They are Borel sets).

The assumption that a local continuous section $s$ exists is weak. It is always satisfied in the context of Lie groups. The reason is that for a Lie group $G$ there is a vector space $\mathfrak{g}$ (the Lie-algebra) and a surjective map $\mathfrak{g} \to G$ which is a local homeomorphism close to the origin. Even more, there exists a subspace $\mathfrak{p} \subset \mathfrak{g}$ which plays the same role for $P$. Consider a decomposition of vector spaces $\mathfrak{g} = \mathfrak{p} \oplus \mathfrak{a}$. Then $\mathfrak{a} \to P \setminus G$ is a local homeomorphism close to the origin. Now the existence of a local section is clear, it just corresponds to the natural imbedding of $\mathfrak{a}$ into $\mathfrak{g}$.

This argument applies in all situations which we need. In the following we take Assumption 2.1 to be granted. We need a generalization of the construction of quotient measures (Proposition I.4.3).
2.3 Proposition. Assume that $P \subset G$ is a closed subgroup of a locally compact group and that $q$ is a function as in Assumption 2.1. Then there exists a unique Radon measure $d\bar{x}$ on $P \setminus G$ (depending on $q$) such that the formula
\[
\int_G f(x)q(x)d\lambda x = \int_{P \setminus G} \left[ \int_P f(px)d\nu_x \right] d\bar{x}
\]
holds for $f \in C_c(G)$. Here $d\nu_x$ denotes a right invariant measure on $P$, and $d\lambda x$ a left invariant measure on $G$ (suitably normalized).

The proof is the same as that of the existence of the quotient measure, Proposition 1.4.3 (which we did not give in full detail). We just mention the essential fact that the inner integral is left invariant as function of $x$, since $d\nu_x$ has been taken to be right invariant. We also mention that for $f \in C_c(G)$, the function $f(x)q(x)$ is an integrable function on $G$ (with respect to any Radon measure).

Usually we will write $dx$ instead of $d\bar{x}$ as long this is not expected to cause confusion.

This measure on $P \setminus G$ is not invariant under the action of $G$. But it has still the weaker problem that the space of zero functions is invariant under (right) translation with elements of $G$.

One can use this measure to define the induced representation of a unitary representation $\sigma : P \to \text{GL}(H)$.

2.4 Definition and Remark. Assume that $P \subset G$ is a closed subgroup of a locally compact group and that $q$ is a function as in Assumption 2.1. Let $dx$ be the corresponding measure on $P \setminus G$. Let $\sigma : P \to \text{GL}(H)$ be a unitary representation. Consider the space of all measurable functions $f : G \to H$ with the property $f(px) = \sigma(p)f(x)$ and such that $\|f(x)\|_\sigma^2$ is integrable considered as function on $P \setminus G$. The quotient of this space by the subspace of all functions, such that $\|f(x)\|_\sigma^2$ is a zero function (considered on $P \setminus G$), is a Hilbert space $H(\sigma)$ with the Hermitian inner product
\[
\langle f, g \rangle = \int_{P \setminus G} \langle f(x), g(x) \rangle_\sigma dx.
\]

The group $G$ acts on it by means of the modified translation from the right: for $g \in G$ the operator $R_g$ is defined by
\[
(R_g f)(x) = f(xg)(q(xg)/q(x)).
\]

This is a unitary representation, called the (unitary) induced representation of $\sigma$ to $G$. It is independent of the choice of $q$ up to unitary isomorphism.
3. Stone’s theorem

We study unitary representations of the additive group \( \mathbb{R}^n \) which are not necessarily irreducible. We give an example. Let \((X, dx)\) be a Radon measure and \(f : X \to \mathbb{C}\) be a measurable and bounded function. Then we can define the multiplication operator

\[
m_f : L^2(X, dx) \to L^2(X, dx), \quad g \mapsto fg.
\]

This is a bounded linear operator. A bound is given by \(\sup_{x \in X} |f(x)|\). The adjoint of \(m_f\) is \(m_{\bar{f}}\). Hence \(m_f\) is self-adjoint for real \(f\) and unitary if \(|f(x)| = 1\) for all \(x\). If \(f\) is the characteristic function of a measurable set, we have \(m_f^2 = m_f\). This means that \(P = m_f\) is an orthogonal projection. This implies that there exists an orthogonal decomposition \(H = H_1 \oplus H_2\) such that \(P(h_1 + h_2) = h_2\). Just take for \(H_1\) the kernel of \(P\) and for \(H_2\) its orthogonal complement. This is the image of \(P\).

If \(f_n\) is a sequence of uniformly bounded functions that converges pointwise to \(f\) then \(m_{f_n}\) converges pointwise to \(m_f\).

Now we assume that \(f : X \to \mathbb{R}^n\) is a measurable (not necessarily bounded) function. Then we can consider for each \(a \in \mathbb{R}^n\) the bounded and measurable function

\[
x \mapsto e^{i \langle a, f(x) \rangle} \quad ((a, b) = a_1 b_1 + \cdots + a_n b_n).
\]

We denote by \(U(a)\) the multiplication operator for this function. Obviously this is an unitary operator and moreover \(a \mapsto U(a)\) is an unitary representation. We call it the multiplication representation related to \(f\).

3.1 Stone’s theorem. Let \(U : \mathbb{R}^n \to \text{GL}(H)\) be a unitary representation. Then there exists a Radon measure \((X, dx)\) and a continuous function \(f : X \to \mathbb{R}^n\) and a Hilbert space isomorphism \(\sigma : H \to L^2(X, dx)\) such that the transport of \(U\) to \(L^2(X, dx)\) equals the multiplication representation related to \(f\).

The space \((X, dx)\) is not uniquely determined.

In the following we use the notations of Stone’s theorem. We consider a bounded function \(\varphi : \mathbb{R}^n \to \mathbb{C}\). We always assume that \(\varphi \circ f\) is measurable with respect to \(dx\). This is for example the case when \(\varphi\) is continuous. Another case which we will use is that \(\varphi\) is the characteristic function of a Borel set \(B \subset \mathbb{R}^n\), since then \(\varphi \circ f\) is the characteristic function of \(f^{-1}(B)\) which is also a Borel set. Then we can consider the multiplication operator \(m_{\varphi \circ f}\). We use the isomorphism in Theorem 3.1 to transport it to a bounded linear operator which we denote by same letter

\[
M_\varphi = m_{\varphi \circ f} : H \to H.
\]

3.2 Remark. The operator \(M_\varphi\) depends only on the representation \(U(a)\) and the function \(\varphi\) (and not on the choice of \((X, dx)\) and the isomorphism \(\sigma\)).
We omit the proof since we do not need in what follows.

In the special case that \( \varphi(x) = e^{2\pi i \langle a, x \rangle} \), we get back \( M_\varphi = U(a) \). If \( \varphi \) is the characteristic function of a Borel set \( B \subset \mathbb{R}^n \), we denote this operator by

\[
M(B) = M_\varphi : H \rightarrow H.
\]

3.3 Lemma. We use the notations of Theorem 3.1. The map \( B \rightarrow M(B) \) from Borel sets to orthogonal projection operators on \( H \) has the following properties.

1) \( M(\emptyset) = 0 \).
2) \( M(\mathbb{R}^n) = \text{id} \).
3) Let \( B = B_1 \cup B_2 \cup \ldots \) by a disjoint union of countable many Borel sets. Then

\[
M(B) = \sum M(B_n)
\]
(pointwise convergence of operators).

Usually \( M \) is called a the “spectral measure” of the representation \( U \).

4. Mackey’s theorem

Let \( G \) be a locally compact group and let \( L, A \) be two closed subgroups. We assume that \( A \) is an abelian normal subgroup and that the map

\[
L \times A \rightarrow G, \quad (h, a) \mapsto ha,
\]
is topological. Then \( L \) acts on \( A \) by conjugation \( gag^{-1} \). We are interested in continuous characters

\[
\alpha : A \rightarrow S^1.
\]
They form a group \( A' \). The group \( L \) acts on \( A' \) in an obvious way. Two characters \( \alpha, \beta \) are called equivalent if there exists \( g \in L \) such that \( \beta = g(\alpha) \). This means

\[
\beta(a) = \alpha(gag^{-1}).
\]
The equivalence classes with respect to this equivalence relation are called orbits. For a character \( \alpha \) we consider the group

\[
L_\alpha = \{ g \in L; \quad \alpha(gag^{-1}) = \alpha(g) \}.
\]
This group depends essentially only on the orbit of \( \alpha \). This means the following. Let \( \beta = g(\alpha) \) be another character in the orbit. Then

\[
L_\beta = gL_\alpha g^{-1}.
\]
The subgroups of $L$ of the form $L_\alpha$ are called little subgroups of $L$. They are determined through $L$ and the action of $L$ on $A$.

Now we consider an irreducible unitary representation

$$\sigma : L_\alpha \rightarrow \text{GL}(H).$$

We can extend this to a representation

$$\sigma \cdot \alpha : L_\alpha A \rightarrow \text{GL}(H), \quad (x, a) \mapsto \alpha(a)\sigma(x).$$

We can induce this representation to an unitary representation of $G$. We say that a unitary representation of $G$ comes from a pair $(L_\alpha, \sigma)$ if it is isomorphic to the representation constructed in this way.

Mackey’s theorem states that – under a certain assumption – this is an irreducible unitary representation of $G$ and that each irreducible unitary representation is isomorphic to such one.

We now explain this assumption. For this we have to know that $A'$ carries a structure of a locally compact group as well. For our purposes the case $A = \mathbb{R}^n$ is enough. Hence we will only explain this for this group

4.1 Lemma. Let $(\cdot, \cdot)$ be any non-degenerated bilinear form on $\mathbb{R}^n$. Every continuous character on $\mathbb{R}^n$ is of the form

$$L : \mathbb{R}^n \rightarrow S^1, \quad L(x) = e^{i(a,x)} \quad (a \in \mathbb{R}^n).$$

This gives an isomorphism

$$\mathbb{R}^n \rightarrow (\mathbb{R}^n)', \quad a \mapsto L.$$

We use this isomorphism to equip $(\mathbb{R}^n)'$ with a topology. Of course this topology is independent on the choice of $(\cdot, \cdot)$. Using this isomorphism we can identify $\mathbb{R}^n$ with its dual. It is the same to consider the orbits of $L$ in $\mathbb{R}^n$ or in the dual.

Now we can formulate the assumptions for Mackey’s theorem.

4.2 Assumption. There exists a closed subset in $A'$ which intersects with each orbit in exactly one point.

This means that we can choose from each orbit a representative in some regular way.

Now we can formulate Mackey’s theorem.
4.3 Mackey’s theorem. Assume that $G = LA$ satisfies the assumption.

Then each unitary representation of $G$ that comes from an irreducible unitary representations of a little groups is unitary and irreducible. Each irreducible unitary representation of $G$ is isomorphic to one of this type.

One can ask when two irreducible representations of $G$ are isomorphic.

4.4 Theorem, Mackey. Two irreducible unitary representations that come from pairs $(L_\alpha, \sigma), (L_\beta, \tau)$ are (unitary) isomorphic if and only if there exist $g \in L, \beta = g(\alpha)$ and a commutative diagram

$$
\begin{array}{ccc}
L_\alpha & \rightarrow & \text{Un}(H_\alpha) \\
\downarrow & & \downarrow \\
L_\beta & \rightarrow & \text{Un}(H_\beta)
\end{array}
$$

The right vertical arrow has to come from a Hilbert space isomorphism $H_\alpha \to H_\beta$.

Hence we can choose a system $S$ of representatives of the orbits and then write

$$
\hat{G} \cong \bigcup_{\alpha \in S} \hat{L}_\alpha.
$$

This means that we have to determine a system of representatives of the orbits and the irreducible unitary representations of the corresponding little groups.

An example

We consider the group

$$
\text{Iso}(2) := \left\{ \begin{pmatrix} \zeta & z \\ 0 & \zeta^{-1} \end{pmatrix} ; \ \zeta \in S^1, z \in \mathbb{C} \right\}.
$$

(Its name will be explained later.) The subgroup $L$ is defined through $z = 0$ and isomorphic to $S^1$. The subgroup $A$ is defined through $\theta = 0$ and is isomorphic to $\mathbb{C}$. The action of $S^1$ on $\mathbb{C}$ is given by

$$
(\zeta, z) \mapsto \zeta^2 z.
$$

As representatives of the orbits we can take $z = r$ real, $r \geq 0$. The corresponding small group is $S^1$ in the case $r = 0$ and the trivial group $\{1, -1\}$ else. The case $r = 0$ leads to the one dimensional representations that factor through $\text{Iso}(2) \to S^1$. For each $r > 0$ we get one infinite dimensional irreducible representation of $\text{Iso}(2)$. 
4.5 Theorem. The group $\text{Iso}(2)$ has two series of irreducible unitary representations. The first series is parameterized through $\mathbb{Z}$ and corresponds to the one-dimensional characters that factor through $\text{Iso}(2) \to S^1$. The second series is parameterized through $\mathbb{R}_{>0} \times \{1, -1\}$. They all come from the little group $\{1, -1\}$.

We write the representation coming from $(r, \epsilon)$, $r > 0$, explicitly. Here $\epsilon$ as a character of $\{1, -1\}$. It is either the trivial representation or it corresponds to the non-trivial character $\mathbb{Z}/2\mathbb{Z} \to S^1$. Then we have to extend this to the character (one-dimensional representation)

$$\{1, -1\} \times \mathbb{C} \to S^1; \quad (\alpha, z) \mapsto \epsilon(\alpha) e^{i(r,z)}.$$
Chapter V. Unitary representations of the Poincaré group

1. The Lorentz group

The Minkowski space of dimension $n + 1$ is the vector space $\mathbb{R}^{n+1}$ that has been equipped with the symmetric bilinear form
\[
\langle x, y \rangle = -x_1 y_1 + x_2 y_2 + \cdots + x_{n+1} y_{n+1}.
\]
A vector is called time-like if $\langle x, x \rangle = 0$. The set of all time like vectors consists of two connected cones. One of them is defined by $x_1 > 0$. We call this the future cone.

The Lorentz group is the subgroup of $\text{GL}(\mathbb{R}^{n+1})$ that preserves this form, $\langle gx, gy \rangle = \langle x, y \rangle$. If one identifies $\text{GL}(\mathbb{R}^{n+1})$ with $\text{GL}(n + 1, \mathbb{R})$ in the usual manner, then this means
\[
A'JA = J \quad \text{where} \quad J = \begin{pmatrix}
-1 & 1 & & \\
 & 1 & & \\
 & & \ddots & \\
 & & & 1
\end{pmatrix}.
\]

We denote the Lorentz group by $O(n, 1)$. We always assume $n > 0$. There are two important subgroups. The first is the special orthogonal group $SO(n, 1)$ which consists of all elements with determinant one. The second is the subgroup $O^+(n, 1)$ that preserves the future cone. Since time like vectors are mapped to time like vectors, it is sufficient to know that the vector $(1, 0, \ldots, 0)$ is mapped to a vector $a$ with $a_1 \geq 0$. For the matrix $A$ this means that $a_{11} > 0$. Hence we have seen that the set of all matrices in the Lorentz group with this property build a group. The elements of this group are called loxodromic. The matrix $J$ is in the Lorentz group and has determinant $-1$. This shows
\[
O(n, 1) = SO(n, 1) \cup SO(n, 1)J.
\]

The negative of the unit matrix $E$ is not loxodromic. Hence we see
\[
O(n, 1) = O^+(n, 1) \cup O^+(n, 1)(-E).
\]
§1. The Lorentz group

We use the notation

$$\text{SO}^+(n,1) = \text{O}^+(n,1) \cap \text{SO}(n,1).$$

We see

$$\text{O}(n,1) = \text{SO}^+(n,1) \cup \text{SO}^+(n,1)J \cup \text{SO}^+(n,1)(-E) \cup \text{SO}^+(n,1)(-J).$$

It can be shown that $\text{SO}^+(n,1)$ is open in $\text{O}(n,1)$ and connected. Hence $\text{O}(n,1)$ has 4 connected components.

For small $n$ one can find different descriptions. We start with $\text{O}(2,1)$. For this we consider the vector space $X$ of all skew symmetric real $2 \times 2$-matrices

$$X = \begin{pmatrix} x_2 & x_1 \\ -x_1 & x_3 \end{pmatrix}.$$ Their determinant is $-x_1^2 + x_2^2 + x_3^2$. We identify $X$ with $\mathbb{R}^3$ in the obvious way. The group $\text{SL}(2, \mathbb{R})$ acts on $X$ through $(A,X) \mapsto AXA'$. For given $A$ this transformation can be considered as element of $\text{GL}(3, \mathbb{R})$. The above formula for the determinant shows that it is in $\text{O}(3, \mathbb{R})$. From the Iwasawa decomposition one can see that $\text{SL}(2, \mathbb{R})$ is connected. Hence we constructed a homomorphism $\text{SO}^+(2,1) \rightarrow \text{SL}(2, \mathbb{R})$. This is surjective and each element of the target has two pre-images. Hence we write

$$\text{SL}(2, \mathbb{R}) = \text{Spin}(2,1).$$

1.1 Proposition. The homomorphism $G \to \text{SO}^+(n,1)$ is continuous and surjective. Each element of $\text{SO}^+(2,1)$ has precisely two inverse images which differ only by the sign.

We skip the proof of the surjectivity. □

Proposition 1.1 is only a special case of a general result. For each $n$ there exists connected locally compact group $G$ and a continuous surjective homomorphism $G \to \text{SO}^+(n,1)$ such that each element of the image has precisely two pre-images. This group is (in an obvious sense) essentially unique and called the spin covering. The usual notation is $\text{Spin}(n,1)$ for this group. We don’t give this (not quite trivial construction) in the general case and treat besides $n = 2$ only the case $n = 3$ which is fundamental for physics.

Similar constructions hold for the compact groups $\text{O}(n)$, $n > 1$. It is known that $\text{SO}(n)$ is already connected (there are no plus groups in this case). The spin group in this case is a connected group $\text{Spin}(n)$ together with a continuous
homomorphism $\text{Spin}(n) \to \text{SO}(n)$ such that each element of the target has precisely two pre images.

So far we constructed $\text{Spin}(2,1) = \text{SL}(2,\mathbb{R})$. For the construction of $\text{Spin}(3,1)$ we consider the space of all Hermitian $2 \times 2$-matrices

$$H = \begin{pmatrix} h_0 & h_1 \\ \bar{h}_1 & h_2 \end{pmatrix}.$$ 

We identify $\mathcal{H}$ with $\mathbb{R}^4$ through

$$H \mapsto \left( \frac{h_0 + h_2}{2}, \frac{h_0 - h_2}{2}, \text{Re} h_1, \text{Im} h_1 \right).$$

Then we have

$$\det H = x_1^2 - x_2^2 - x_3^2 - x_4^2.$$ 

The group $\text{SL}(2,\mathbb{C})$ acts on $\mathcal{H}$ through $(A,H) \mapsto A H \bar{H}'$ It preserves the determinant. Hence we obtain a Lorentz transformation. It can be shown that $\text{SL}(2,\mathbb{C})$ is connected two. Hence we get a homomorphism

$$\text{SL}(2,\mathbb{C}) \to \text{SO}^+(3,1).$$

1.2 Proposition. The homomorphism $\text{SpinDr}$

$$\text{SL}(2,\mathbb{C}) \to \text{SO}^+(3,1)$$

is continuous and surjective. Each element of $\text{SO}^+(3,1)$ has precisely two inverse images which differ only by the sign.

This allows us to write

$$\text{Spin}(3,1) = \text{SL}(2,\mathbb{C}).$$

The existence of spin coverings is not tied to signature $(n,1)$. For example we can consider the Euclidian orthogonal group $O(3,\mathbb{R})$. Recall that $O(n,\mathbb{R})$ consists of all $A \in \text{GL}(n,\mathbb{R})$ with the property $A'A = E$. This is a closed subgroup. The rows and columns have Euclidean length 1. Hence $O(n,\mathbb{R})$ is a compact group (in contrast to the Lorentz group!). The subgroup $\text{SO}(n,\mathbb{R})$ of elements of determinant one is called the special orthogonal group. One can show that it is connected. The group $O(n,\mathbb{R})$ can be embedded into the Lorentz group $O(n,1)$ by means of

$$A \mapsto \begin{pmatrix} 1 & 0 \\ 0 & A \end{pmatrix}.$$ 

We consider this in the case $n = 3$. We can consider the inverse image in $\text{SL}(2,\mathbb{C})$. One can check that this inverse image is the special unitary group $\text{SU}(2)$. Recall that The unitary group $U(n)$ is the subgroup of all $A \in \text{GL}(n,\mathbb{C})$ with the property $A'A = E$. This is a compact group. The special unitary group is the subgroup of all $A$ with $\det A = 1$. One can show that it is connected.
1.3 Proposition. The homomorphism

$$\text{SU}(2) \rightarrow \text{SO}(3, \mathbb{R})$$

is continuous and surjective. Each element of \( \text{SO}(3, \mathbb{R}) \) has precisely two inverse images which differ only by the sign.

Hence we can write

$$\text{Spin}(3) = \text{SU}(2, \mathbb{C}).$$

What could be \( \text{Spin}(2) \)? It should be a two fold covering of \( \text{SO}(2, \mathbb{R}) \). This group isomorphic to \( S^1 \). Here we have the natural map

$$S^1 \rightarrow S^1, \quad \zeta \mapsto \zeta^2.$$

Hence it looks natural to define

$$\text{Spin}(2) = S^1$$

together with the map

$$\text{Spin}(2) \rightarrow \text{SO}(2), \quad e^{i\theta} \mapsto \begin{pmatrix} \cos(2\theta) & \sin(2\theta) \\ -\sin(2\theta) & \cos(2\theta) \end{pmatrix}.$$

2. The Poincaré group

In the following we call \( \text{O}(n,1) \) the homogeneous Lorentz group. The inhomogeneous Lorentz group is the set of all transformations of \( \mathbb{R}^{n+1} \) of the form

$$v \mapsto A(v) + b$$

where \( A \) is a Lorentz transformation and \( b \in \mathbb{R}^{n+1} \). This group can be identified with the set \( \text{O}(n,1) \times \mathbb{R}^{n+1} \). The group law then is

$$(g, a)(h, b) = (gh, a + gb).$$

We write for the inhomogeneous Lorentz group simply

$$\text{O}(n,1)\mathbb{R}^{n+1}.$$
Spin$(n,1) \rightarrow \text{O}(n,1)$ and the natural action of $\text{O}(n,1)$ on $\mathbb{R}^{n+1}$. We write this action simply in the form $(g,v) \mapsto gv$. The Poincaré group $P(n)$ is the set

$$P(n) = \text{Spin}(n,1) \times \mathbb{R}^{n+1}$$

together with the group law

$$(g,a)(h,b) = (gh,a+gb).$$

It is clear that this is a group and that the natural map

$$P(n) \rightarrow \text{O}(n,1)\mathbb{R}^{n+1}$$

(spin covering on the first factor and identity on the second factor) is a homomorphism. This image is $\text{SO}^+(n,1)\mathbb{R}^{n+1}$ and each element has two inverse images.

There is a Euclidian pendent of the inhomogenous Lorentz group. The Euclidian group is the set of all transformations of $\mathbb{R}^n$ of the form

$$v \mapsto A(v) + b$$

where $A \in \text{O}(n)$ and $b \in \mathbb{R}^n$. This group can be identified with the set $\text{O}(n) \times \mathbb{R}^n$. The group law then is

$$(g,a)(h,b) = (gh,a+gb).$$

We write for the inhomogeneous Lorentz group simply

$$E(n) = \text{O}(n)\mathbb{R}^n$$

and

$$E_0(n) = \text{SO}(n)\mathbb{R}^n.$$

**Orbits**

The Lorentz group $\text{O}(3,1)$ acts on $\mathbb{R}^4$ in a natural way. Two elements $a,b$ are in the same orbit if and only if $\langle a,a \rangle = \langle b,b \rangle$. Here $\langle \cdot,\cdot \rangle$ means the Lorentz scalar product. It is easy to derive a system of representatives of the orbits and the corresponding stabilizers.

**Representatives of orbits and their stabilizers for the Lorentz group**

(natural action of $\text{O}(3,1)$ on $\mathbb{R}^4$)

1) $(0,0,0,0)$ \hspace{1cm} $\text{O}(3,1)$
2) $(0,m,0,0)$, $m > 0$ \hspace{1cm} $\text{O}(2,1)$
3) $(m,0,0,0)$, $m > 0$ \hspace{1cm} $\text{O}(3)$
4) $(1,1,0,0)$ \hspace{1cm} $E(2)$
3. The Poincaré group

The subgroup SO(3, 1) has the same orbits since the representatives are fixed by substitution that has determinant $-1$. Simply change the sign of the last coordinate. But this is not true if one takes SO$^+(3, 1)$. Here the representatives are as follows.

**Representatives of orbits and their stabilizers for the restricted Lorentz group**
(natural action of SO$^+(3, 1)$ on $\mathbb{R}^4$)

1) $\begin{pmatrix} 0, 0, 0, 0 \end{pmatrix}$ SO$^+(3, 1)$
2) $\begin{pmatrix} 0, m, 0, 0 \end{pmatrix}$, $m > 0$ SO$^+(2, 1)$
3) $\begin{pmatrix} 0, m, 0, 0 \end{pmatrix}$, $m < 0$ SO$^+(2, 1)$
4) $\begin{pmatrix} m, 0, 0, 0 \end{pmatrix}$, $m > 0$ SO(3)
5) $\begin{pmatrix} 1, 1, 0, 0 \end{pmatrix}$, $m > 0$ E$_0(2)$
6) $\begin{pmatrix} -1, 1, 0, 0 \end{pmatrix}$, $m > 0$ E$_0(2)$

Finally we treat the action of SL(2, C) on $\mathbb{R}^4$. The orbits are the same as that of SO$^+(3, 1)$. The stabilizers are the inverse images of the stabilizers in SO$^+(3, 1)$.

**Representatives of orbits and their stabilizers for the Spin group**
(natural action of SL(2, C) on $\mathbb{R}^4$)

1) $\begin{pmatrix} 0, 0, 0, 0 \end{pmatrix}$ SL(2, C)
2) $\begin{pmatrix} 0, m, 0, 0 \end{pmatrix}$, $m > 0$ SL(2, R)
3) $\begin{pmatrix} 0, m, 0, 0 \end{pmatrix}$, $m < 0$ SL(2, R)
4) $\begin{pmatrix} m, 0, 0, 0 \end{pmatrix}$, $m > 0$ SU(2)
5) $\begin{pmatrix} 1, 1, 0, 0 \end{pmatrix}$, $m > 0$ Iso(2)
6) $\begin{pmatrix} -1, 1, 0, 0 \end{pmatrix}$, $m > 0$ Iso(2)

Here Iso(2) means the inverse image of E$_0(2)$ in SL(2, C). Hence we see that the irreducible unitary representations of the Poincaré group come from the irreducible unitary representations of the little groups

SL(2, C),  SL(2, R) two possibilities,  SU(2),  Iso(2) two possibilities.

They have been all determined in the book. Not all irreducible representations of P(3) are of physical significance.

There is the notion of “positive energy” for an irreducible unitary representation of P(3). The definition needs rest on the Hamilton operator which we will introduce a little later (Definition 5.3.3). Here we just mention that the cases 4) and 5) lead to representations of positive energy. These are the representations of physical interest. In both cases $\langle a, a \rangle$ is non-positive and we can define the mass of such a representation by

$$m := \sqrt{-\langle a, a \rangle}.$$ 

So we have
$a = (0, m, 0, 0)$ representation of positive energy and mass $m > 0$,
$a = (1, 1, 0, 0)$ representation of positive energy and mass $m = 0$.

These representations come from the small groups SU(2) and Iso(2).

## 3. Physical relevance

We keep short.

**Special relativity**

*Minkowski space.* The space of all space time events. It is a four dimensional real vector space.

*Observer.* An isomorphism $M \cong \mathbb{R}^4$. So any event corresponds to a point $(x_0, x_1, x_2, x_3)$, $x_0$ is the time coordinate and the other are the space coordinates.

*Change of an observer.* An isomorphism $\mathbb{R}^4 \rightarrow \mathbb{R}^4$. It preserves the form $-x_0^2 + x_1^2 + x_2^2 + x_3^2$. The set of all possible changes of observers is the Lorentz group $O(3, 1)$.

**Quantum Mechanics**

*The physical Hilbert space $\mathcal{H}.* An observer sees states, these are elements of the associated projective space $\hat{\mathcal{H}} = (\mathcal{H} - \{0\})/\mathbb{C}^*$. Change of an observer induces a bijection $\hat{\mathcal{H}} \rightarrow \hat{\mathcal{H}}$. The transition probabilities

$$\frac{(\phi, \psi)}{||\phi||^2||\psi||^2}$$

are preserved. The set of all these maps is denoted by $\text{Aut}(\hat{\mathcal{H}})$.

*Change of observers.* This given by a homomorphism

$$G \cong O^+(1, 3) \times M \rightarrow \text{Aut}(\hat{\mathcal{H}}).$$

Special elements of $\text{Aut}(\hat{\mathcal{H}})$ come from unitary operators $U : \mathcal{H} \rightarrow \mathcal{H}$. But also antiunitary operators induce elements of $\text{Aut}(\hat{\mathcal{H}})$. Wigner has shown that each element of $\text{Aut}(\hat{\mathcal{H}})$ comes from a unitary or antiunitary operator. Hence The image of

$$\text{Un}(\mathcal{H}) \rightarrow \text{Aut}(\hat{\mathcal{H}})$$

is a subgroup of index two. One can show that the image of $SO^+(3, 1)$ is contained in this subgroup. Such a homomorphism usually can not be lifted to a homomorphism into $\text{Un}(\mathcal{H})$ But now the Poincaré group
comes into the game. A not quite trivial theorem says that there exists a homomorphism of the Poincaré group $P \to U(H)$ such that the diagram

\[
P \quad \rightarrow \quad U(H) \\
\downarrow \quad \downarrow \\
G \quad \rightarrow \quad \text{Aut}(H)
\]

commutes. Hence a unitary representation of the Poincaré group is basic for the (special) relativistic Quantum Mechanics.

**The Poincaré algebra**

We start with some remarks about Lie groups and Lie algebras. There is no need to prove them here, since in all cases we need them, one can verify them directly.

Let $G, H$ be two Lie groups (one of the groups we consider) and let $G \to H$ be a continuous homomorphism. One can show that there exists a unique homomorphism of Lie algebras $g \to h$ such that the diagram

\[
G \quad \rightarrow \quad H \\
\uparrow \quad \uparrow \\
g \quad \rightarrow \quad h
\]

commutes. In the case that the fibres of $G \to H$ are discrete (for example finite) this map is injective and even more an isomorphism if their dimensions agree. Examples are our spin coverings, for example

\[\text{SL}(2, \mathbb{C}) \to \text{SO}(3, 1).\]

The induced homomorphism of Lie algebras $\mathfrak{sl}(2, \mathbb{C}) \to \mathfrak{s}(3, 1)$ must be an isomorphism. It is a good exercise to work it out. Similarly $\mathfrak{su}(2) \cong \mathfrak{so}(3)$, and so on. Another observation is that a Lie group $G$ has the same Lie algebra as its connected component. Roughly speaking: the Lie algebra cannot see discrete stuff.

Next we consider the extended Lorentz group. We want to consider as a matrix group. For this we consider $O(3, 1)_{\mathbb{R}^4} \to \text{GL}(5, \mathbb{R})$, $(g, a) \mapsto \begin{pmatrix} g & a \\ 0 & 1 \end{pmatrix}$.

This defines an isomorphism of the extended Lorentz group with a closed subgroup of $\text{GL}(5, \mathbb{R})$. Hence the Lie algebra is defined. Following our general remarks, the groups $\text{SO}^+(3, 1)_{\mathbb{R}^4}$ and the Poincaré group $P(3)$ should have the same Lie algebra. We skip the direct construction of the Lie algebra $\mathfrak{p}$ of $P(3)$ and just define

\[\mathfrak{p} := \text{Lie algebra of the extended Lorentz group}.\]
Besides \( \mathfrak{p} \) we also consider its complexification \( \mathfrak{p}_\mathbb{C} = \mathfrak{p} + i\mathfrak{p} \). From definition, \( \mathfrak{p} \) consists of all real \( 5 \times 5 \)-matrices \( \tilde{A} \) such that \( \exp(t\tilde{B}) \) is in the group. It is easy to check that \( \tilde{B} \) is of the form

\[
\tilde{A} = \begin{pmatrix} A & a \\ 0 & 0 \end{pmatrix},
\]

One computes the Lie bracket as

\[
[\tilde{A}, \tilde{B}] = \begin{pmatrix} [A, B] & Ab - Ba \\ 0 & 0 \end{pmatrix}.
\]

This shows that we can identify \( \mathfrak{p} \) with pairs \((A, a)\). We take this description now as final definition

\begin{definition}
The Poincaré algebra \( \mathfrak{p} \) is as vector space

\[
\mathfrak{p} := \mathfrak{so}(3, 1) \times \mathbb{R}^4
\]

with the Lie bracket

\[
[[A, a], (B, b)] = ([A, B], Ab - Ba).
\]

In this formula \(a, b\) is understood as column vector.
\end{definition}

The natural embedding

\[
\mathfrak{so}(3, 1) \rightarrow P, \quad A \mapsto (A, 0)
\]

is a Lie homomorphism. Hence \( \mathfrak{so}(3, 1) \) can be considered as Lie sub-algebra of \( \mathfrak{p} \). Similarly \( \mathbb{R}^4 \) can be considered as subspace of \( \mathfrak{p} \), via \( a \mapsto (0, a) \). We can consider \( \mathbb{R}^4 \) as Lie sub-algebra if we equip it with the trivial structure \([A, B]\). (On calls then \( \mathbb{R}^4 \) an abelian sub-algebra.)

The dimension of \( \mathfrak{p} \) is obviously 10. It is easy to write down a basis. In the following we denote the coordinates of \( \mathbb{R}^4 \) by \((x_0, \ldots, x_3)\) and we denote the standard basis of \( \mathbb{R}^4 \) by \( e_0, \ldots, e_4 \). Similarly the labels of matrices run form 0 to 3.

First we consider the standard basis \( e_0, \ldots, e_4 \) of \( \mathbb{R}^4 \) and consider them as elements of \( \mathfrak{p} \). Then we recall that the elements of \( \mathfrak{so} \) are of the form

\[
E_{3,1}A, \quad A' = -A, \quad E_{3,1} = \begin{pmatrix} -1 & 1 \\ 1 & 1 \end{pmatrix}.
\]
We denote by \( \omega^{(ij)} \) for \( 0 \leq i < j \leq 3 \) the skew symmetric matrix that has entry 1 at the position \((i, j)\) and \(-1\) at the position \((j, i)\) den den und zeros else.

The 10 elements \( e_i \in M \) and \( E_{3,1} \omega^{(ij)} \in p \) form a (real) basis of \( p \). Of course the form also a \( C \)-basis of \( p_C \).

Physicists use a slight modification. They use

\[
P^i = -ie_i, \quad J^{ij} = \frac{1}{2} \omega^{ij}.
\]

**3.2 Remark.** The 10 elements \( P^i, J^{ij} \) form a complex basis of \( p_C \). The commutation rules

\[
\begin{align*}
    i[J^{\mu\nu}, J^{\rho\sigma}] &= \eta^{\nu\rho} J^{\mu\sigma} - \eta^{\mu\rho} J^{\nu\sigma} + \eta^{\sigma\mu} J^{\nu\rho}, \\
    i[P^\mu, J^{\rho\sigma}] &= \eta^{\mu\rho} P^{\sigma} - \eta^{\mu\sigma} P^{\rho}, \\
    [P^\mu, P^\rho] &= 0.
\end{align*}
\]

determine the structure of the Poincaré algebra.

If we have a unitary representation of the Poincaré group on the Hilbert space \( \mathcal{H} \), we can define as earlier the dense subspace of differentiable vectors. The elements of \( p \) and then, by \( C \)-linear extension, then induce operators \( H^\infty \to H^\infty \). This operators often are denoted by the same letter, and, even more, the elements of \( p \) are called “operators”. Their physical names are:

- Hamilton operator \( H = P^0 \)
- Momentum operators \( P := (P^1, P^2, P^3) \)
- Angular momentum operators \( J := (J^{23}, J^{31}, J^{12}) \)
- Boost operators \( K := (J^{01}, J^{02}, J^{03}) \)

The Hamilton operator commutes with momentum and angular momentum operators, but not with the boost operators.

The Hamilton operator is of great importance for the study of unitary representations \( P(3) \to \text{Un}(\mathcal{H}) \). The corresponding operator \( H : H^\infty \to H^\infty \) is symmetric,

\[
\langle Ha, b \rangle = \langle a, Hb \rangle \quad \text{for} \ a, b \in H^\infty.
\]

Hence \( \langle Ha, a \rangle \) is real for all \( a \in H^\infty \).

**3.3 Definition.** The unitary representation \( P \to \text{Un}(\mathcal{H}) \) is of positive energy if the exists \( \varepsilon > 0 \) such that

\[
\langle Ha, a \rangle \geq \varepsilon \langle a, a \rangle.
\]

The eigen values of \( H \) for a representation of positive energy are all positive.
Chapter VI. Appendices

1. The spectral theorem

We have to consider the space $\mathcal{C}_c^\infty(\mathbb{R})$ of infinitely many differentiable complex valued functions on the real line. By a “Radon measure on $\mathcal{C}_c^\infty(\mathbb{R})$” we understand a $\mathbb{C}$-linear map $I : \mathcal{C}_c^\infty(\mathbb{R}) \to \mathbb{C}$ with the properties $I(f) = \overline{I(f)}$ and $I(f) \geq 0$ if $f \geq 0$. It is easy to show that such an $I$ extends uniquely to a Radon measure (on $\mathcal{C}_c(\mathbb{R})$). This follows from the fact that each $f \in \mathcal{C}_c(\mathbb{R})$ is the uniform limit of a sequence $f_n \in \mathcal{C}_c^\infty(\mathbb{R})$ whose supports are contained in a joint compact set.

A function $f : \mathbb{R} \to \mathbb{C}$ is called rapidly decreasing if $Pf$ is bounded for all polynomials $P$. If $f$ is measurable and rapidly decreasing, the (usual Lebesgue) integral

$$\int_{-\infty}^{\infty} f(t) dt$$

exists. A function is called tempered (or a Schwartz function) if it is infinitely often differentiable and if all derivatives are rapidly decreasing. The space of all tempered functions is called by $S(\mathbb{R})$. For tempered functions $f$ the Fourier transform

$$\hat{f}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-itx} f(t) dt$$

exists. It is easy to show (using partial integration) that it is tempered again. In particular, the Fourier transform of a $C^\infty$-function with compact support is tempered.

1.1 Fourier inversion theorem. The map $S(\mathbb{R}) \to S(\mathbb{R})$, $f \mapsto \hat{f}$, is an isomorphism of vector spaces. It extends to an isomorphism of Hilbert spaces

$$\mathcal{F} : L^2(\mathbb{R}, dt) \longrightarrow L^2(\mathbb{R}, dt)$$

where $dt$ means the standard Lebesgue measure on the line. Moreover, one has

$$\mathcal{F}\mathcal{F}(f)(x) = f(-x).$$
1. The spectral theorem

Let \((X, dx)\) be Radon measure and let \(f : X \to \mathbb{C}\) be a bounded measurable function. Then we can define a bounded and linear operator

\[ L^2(X, dx) \longrightarrow L^2(X, dx), \quad g \mapsto fg. \]

In the case \(\bar{f}f = 1\) this operator is unitary.

1.2 Spectral theorem. Let \(U : \mathbb{R} \to \text{Un}(H)\) be a unitary representation of the additive group \(\mathbb{R}\) on a Hilbert space. Then there exists a Radon measure \((X, dx)\) and a real continuous function \(f : X \to \mathbb{R}\) such that the representation \(U\) is equivalent to the representation \(\tilde{U} : \mathbb{R} \longrightarrow \text{Un}(L^2(X, dx))\), \(\tilde{U}(t)(g) = e^{itf}g\).

Equivalence means of course that there exists a Hilbert space isomorphism \(W : L^2(\mathbb{R}, dx) \sim \longrightarrow H\) with the property \(\tilde{U}(t) = W^{-1}U(t)W\).

We first treat a reduction of the spectral theorem to a special case. Let \(\pi : G \to \text{GL}(E)\) be a continuous representation. A vector \(a\) is called cyclic if the subspace generated by all \(\pi(g)a\) is dense in \(E\). This means that \(E\) is the only closed invariant subspace that contains \(a\). The representation is (topologically) irreducible if and only if each non zero vector is cyclic. The existence of a cyclic vector is a much weaker condition.

When a cyclic vector exists, then the spectral theorem can be sharpened slightly as follows.

1.3 Proposition. Let \(U : \mathbb{R} \to \text{Un}(H)\) a unitary representation of the additive group \(\mathbb{R}\) on a Hilbert space. Assume that a cyclic vector exists. Then in the spectral theorem we can take \(X = \mathbb{R}\) (and \(dx\) some Radon measure) and \(f(t) = t\).

We first show that the general spectral theorem follows from Proposition 1.3 and hence after we prove the proposition.

Proposition 1.3 implies the spectral theorem 1.2. We claim the following.

Every unitary representation \(\pi : G \to \text{Un}(H)\) has the following property. \(H\) can be written as direct Hilbert sum of a finite or countable set of sub Hilbert spaces \(H_i\) which are invariant and such that each of them admits a cyclic vector.

This can be proved by a standard argument using Zorn’s lemma. We leave the details to the reader. Such a decomposition is not at all unique. Hence one should not over emphasize its meaning.

The Radon measure that is used for the spectral theorem of \((\pi, H)\) is the direct sum of the Radon measures for the single \(H_i\). We explain briefly the notion of the direct sum. Let \((X_i, dx_i)\) be a finite or countable collection of
Radon measures. Then one defines their direct sum as follows. One takes the disjoint union $X$ of the $X_i$. This is the set of all pairs $(x, i), x \in X_i$. There is a natural inclusion $X_i \to X, x \mapsto (x, i)$, and $X$ is the disjoint union of the images. We equip $X$ with the direct sum topology. This means that the (images of the) $X_i$ are open subsets and that the induced topology is the original one. Then one defines in an obvious way a Radon measure on $X$ such that the restriction to the $X_i$ are the given $dx_i$.

Proof of Proposition 1.3. To any bounded continuous function $h : \mathbb{R} \to \mathbb{C}$ we associate the functional

$$I_h : C^\infty_c(\mathbb{R}) \to \mathbb{C}, \quad I_h(g) = \int_{-\infty}^{\infty} h(t) \hat{g}(t) dt.$$ 

The integral exists, since $\hat{g}$ and hence $hg$ are rapidly decreasing. We apply this to the function $h(t) = \langle U(t)a, a \rangle$ where $a$ is a cyclic vector. This function has the property

$$h(-t) = \langle U(-t)a, a \rangle = \langle a, U(t)a \rangle = \overline{h(t)}.$$ 

Using this it is easy to check that $I_h$ is real, i.e. real valued for real $h$. We will see a little that $I_h$ is actually a Radon measure on $C^\infty_c(\mathbb{R})$. For this reason, we later use already now the notation

$$\int_{\mathbb{R}} g(x) d\mu = \int_{-\infty}^{\infty} (U(t)a, a) \hat{g}(t) dt \quad (g \in C^\infty_c(\mathbb{R})).$$

Next we define a linear map

$$W : C^\infty_c(\mathbb{R}) \to H, \quad g \mapsto \int_{-\infty}^{\infty} \hat{g}(t) U(t) dt.$$ 

This is a Bochner integral with values in the Hilbert space $H$. The integrand is continuous, hence measurable and it is bounded by the integrable function $|\hat{g}|$. Hence the Bochner integral exists.

For $g_1, g_2 \in C^\infty_c(\mathbb{R})$ we compute

$$\int_{\mathbb{R}} g_1(t) \overline{g_2(t)} d\mu$$

as follows. We make use of the fact that the Fourier transformation of the product $g_1g_2$ of two functions equals the convolution of the two Fourier transforms

$$\hat{g_1g_2} = \hat{g_1} * \hat{g_2}.$$ 

Recall that the convolution of two functions on the line is

$$(g_1 * g_2)(x) = \int_{-\infty}^{\infty} g_1(x-t)g_2(t) dt.$$
So we get
\[
\int_{\mathbb{R}} g_1(t) \overline{g_2(t)} \, d\mu = \int_{-\infty}^{\infty} \langle U(t)a, a \rangle \overline{\hat{g}_2(t)} \, dt
= \int_{-\infty}^{\infty} \langle U(t)a, a \rangle \int_{-\infty}^{\infty} \hat{g}_1(t-s) \hat{g}_2(s) \, ds.
\]

We compare this with the inner product of \(W(g_1)\) and \(W(g_2)\) in the Hilbert space \(H\). It is
\[
\langle W(g_1), W(g_2) \rangle = \left\langle \int_{-\infty}^{\infty} \langle U(t)a, a \rangle \hat{g}_1(t) \, dt, \int_{-\infty}^{\infty} \langle U(s)a, a \rangle \hat{g}_2(s) \, ds \right\rangle.
\]
The integrals are standard integrals along continuous functions with compact support. They can be considered as Riemann integrals and hence approximated by finite sums. In this way we see
\[
\langle W(g_1), W(g_2) \rangle = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \langle U(t)a, a \rangle \langle U(s)a, a \rangle \hat{g}_1(t) \hat{g}_2(s) \, dt \, ds.
\]

By means of the integral transformation \((t,s) \mapsto (t-s,s)\) we obtain
\[
\int_{\mathbb{R}} g_1(t) \overline{g_2(t)} \, d\mu = \langle W(g_1), W(g_2) \rangle
\]

Now, let \(g \in C_c^{\infty}(\mathbb{R})\) be a real nonnegative function. In the case that \(\sqrt{g}\) is differentiable, we set \(g_1 = g_2 = \sqrt{g}\) to show that \(\int g \, d\mu\) is non negative. But \(\sqrt{g}\) needs not to be differentiable (notice that the square root of \(x^2\) is \(|x|\) which is not differentiable at the origin). But it is always possible to approximate \(g\) by functions \(g_1^2\) where \(g_1\) is differentiable. So we see that \(d\mu\) is a Radon measure as we have claimed. The map \(W : C_c^{\infty}(\mathbb{R}) \to H\) is unitary. Hence it is injective and it extends to a unitary map
\[
L^2(\mathbb{R}, d\mu) \longrightarrow H.
\]

(Here one uses that a bounded linear map \(E \to F\) of normed spaces extends to the completions.) In particular, \(W\) extends to \(S(\mathbb{R})\). The image is a complete and hence a closed subspace of \(H\).

Next we prove \(WU(s) = U(s)W\). This follows simply from the fact that the Fourier transform of the function \(x \mapsto e^{isx}g(x)\) is the function \(x \mapsto \hat{g}(x-s)\).

It remains to show that \(W\) is surjective. Here we have to use that \(a\) is a cyclic vector. It is sufficient that \(a\) is in the image, or even that there exists a sequence \(g_n\) of tempered functions such that \(W(g_n) \to a\). For this purpose we choose a differentiable Dirac sequence \(h_n\). Then the integrals \(\int h_n(t)U(t)a\) converge to \(U(0)a = a\). We can write \(h_n = \hat{g}_n\) where \(g_n\) is tempered. \(\square\)
2. Variants of the spectral theorem

Let \((X, dx)\) be a Radon measure. A function \(f : X \to \mathbb{C}\) is called \textit{essentially bounded} if there exists \(C \geq 0\) such that \(|f(x)| \leq C\) outside a zero set. We denote by \(\|f\|_\infty\) the infimum of all \(C\). This is a semi norm on the space \(L^\infty(X)\) of all measurable essentially bounded \(f\). Zero functions are essentially bounded and their infinity-norm is 0. The quotient \(L^\infty(X)\) of \(L^\infty(X)\) by the subspace of zero functions is a normed space. It can be shown that it is a Banach space.

2.1 Remark. Let \(f\) be an essentially bounded measurable function on \(X\). Then \(gf\) is square integrable if \(g\) is and multiplication by \(f\) defines a bounded linear operator
\[
m_f : L^2(X, dx) \longrightarrow L^2(X, dx).
\]
The norm of \(m_f\) equals \(\|f\|_\infty\).

Proof. Let \(g \in L^2(X, dx)\). Then \(\|fg\|_2 \leq \|f\|_\infty \|g\|_2\). This shows that \(m_f\) is bounded and \(\|m_f\| \leq \|f\|_\infty\). We have to prove the inverse inequality. For this we assume for a moment that \(f\) is square integrable. Then we have \(\|f\|_2^2 = \|fg\|_2^2 \leq \|m_f\| \|f\|_2^2\). This shows \(\|f\|_\infty \leq \|m_f\|\). in the case that \(f\) is not square integrable we replace \(f\) by \(f\chi_K\) where \(\chi_K\) is the characteristic function of a compact subset \(K\). Take the supremum along all \(K\) in the inequality \(\|f\chi_K\|_\infty \leq \|m_f\chi_K\|\) we obtain the claim. \(\square\)

These are the most general multiplication operators due to the following Lemma.

2.2 Lemma. Let \(f\) be an essentially bounded measurable function on \(X\) such that \(fg\) is square integrable if \(g\) is square integrable. Then \(f\) is essentially bounded.

Proof. First we show that multiplication by \(f\) is a bounded operator \(m_f : L^2(X, dx) \to L^2(X, dx)\). Here we use the closed graph theorem. It is enough to show that the graph \((g, fg) : g \in L^2(X)\) is closed. Consider a sequence \((g_n, fg_n)\) that converges in the graph. This means that
\[
g_n \longrightarrow g, \quad fg_n \longrightarrow h \quad (\text{both in } L^2(X, dx)).
\]
Convergence in \(L^2(X, dx)\) implies pointwise convergence of a suitable subsequence outside a zero set. Hence we can assume that \(g_n\) and \(fg_n\) converge pointwise outside the zero set. This shows \(\psi = fg\) in \(L^2(X, dx)\).

The boundedness of \(m_f\) implies the existence of a constant such that
\[
\|fg\|_2 \leq C\|g\|_2.
\]
Now we choose a constant \( A > 0 \) such that \( A^2 > C \). We consider the characteristic function \( \chi \) of the set

\[ \{ x \in X; \ |f(x)| \geq A \}. \]

For a moment we assume that this set has a finite volume. From \( A^2 \chi(x) \leq |f(x)|\chi(x) \) and from \( \chi = \chi^2 \) we obtain

\[ A^2 \int_X \chi(x)dx \leq \int_X |f(x)|\chi(x)^2dx \leq C \int_X \chi(x)dx = C \int_X \chi(x)dx \]

we obtain that \( \chi \) is a zero function. This means that \( |f| \) is bounded by \( A \) outside a zero set.

If \( \chi \) is not integrable, then we make a similar trick as in the proof of Remark 2.1. We multiply \( \chi \) with the characteristic function of an arbitrary compact set \( K \).

We want to work out when \( mf \) is an isomorphism. For this we introduce a notation. Let \( f : X \to \mathbb{C} \) be a measurable function. We say that \( 1/f \) exists if the set of zeros is a zero set. In this case we define

\[ (1/f)(x) = \begin{cases} 1/f(x) & \text{if } f(x) \neq 0, \\ 0 & \text{else.} \end{cases} \]

2.3 Lemma. Let \( f \) be an essentially bounded measurable function on \( X \). The multiplication operator \( mf : L^2(X, dx) \to L^2(X, dx) \) is an isomorphism if and only if \( 1/f \) exists and is essentially bounded.

Proof. Assume that \( mf \) is an isomorphism. Then every \( h \in L^2(X, dx) \) is of the form \( fg, g \in L^2(X, dx) \). In particular \( (1/f)h = g \) is in \( L^2(X, dx) \). Now we can apply Lemma 2.2.

A bounded linear operator \( A : H \to H \) is called self adjoint if \( \langle Ax, y \rangle = \langle x, Ay \rangle \) for all \( x, y \in H \). We derive a spectral theorem for such operators. For this we introduce the exponential

\[ e^A = \sum_{n=1}^{\infty} \frac{A^n}{n!}. \]

This series converges in the Banach space \( \mathcal{B}(H) \), since \( \|A^n\| = \|A\|^n \) and the norm of \( e^A \) is bounded by \( e^{\|A\|} \). As for complex numbers one can prove

\[ e^{A+B} = e^Ae^B \text{ if } AB = BA. \]

Using this one can show that

\[ U(t) = e^{itA} \]
is a unitary representation of $\mathbb{R}$ on $H$. We can apply the spectral theorem 1.2. It says that there exists a Radon measure $(X, dx)$, an isomorphism $H \to L^2(X, dx)$ and a continuous function $f$ such that $U(t)$ corresponds to multiplication with $e^{itf}$ on $L^2(X, dx)$. We want to follow that

$$Ag = fg \quad \text{on} \quad L^2(X, dx)$$

For this we consider a sequence $t_n \to 0$, $t_n \neq 0$. Then

$$\lim_{n \to \infty} \frac{e^{it_nA}g - g}{t_n} = A_n g.$$ 

This holds in $L^2(X, dx)$ but then, after replacing $t_n$ by a subsequence, pointwise outside a zero set. Since we have also

$$\lim_{n \to \infty} \frac{e^{it_nf(x)}g(x) - g(x)}{t_n} = f(x)g(x)$$

we get

$$Ag = fg \quad \text{on} \quad L^2(X, dx)$$

as stated. This implies that $f$ is essentially bounded. So we obtain the following variant of the spectral theorem.

2.4 Theorem. Assume that $A$ is a self adjoint (bounded) operator on a Hilbert space. Then there exists a Radon measure $(X, dx)$, a real continuous and essentially bounded function $f$ on $X$, and a Hilbert space isomorphism $H \cong L^2(X)$ such that $A$ corresponds to multiplication by $f$.

The spectral theorem of compact self adjoint operators (Theorem I.7.3) is a special case of this. To prove it we have to study when a multiplication operator $m_f : L^2(X) \to L^2(X)$ for a real bounded continuous function is compact. A necessary condition for this is that $X$ carries the discrete topology. In particular $X$ must be a countable set. The measure is known if one knows the masses ($=$volumes) $m(a)$ of the single points. The set of all points with mass zero is a zero set. Hence we can replace $X$ by their complement. without changing $L^2(X)$. This means that we can assume $m(a) > 0$ for all $a$. We then consider the functions

$$f_a(x) = \begin{cases} 1/m(a) & \text{for } x = a, \\ 0 & \text{else} \end{cases}$$

This is an orthonormal basis. The functions $f_a$ are eigen functions of $m_f$ with eigen value $f(a)$. So we have proved.

Let $A : H \to H$ be a compact self adjoint bounded operator on a Hilbert space. Then there exists an orthonormal basis $e_1, e_2, \ldots$ of eigen vectors, $Ae_i = \lambda_i e_i$.

We notice that the eigenvalues are bounded. This follows easily from $\|\lambda a\| \leq \|Aa\| \leq \|A\|\|a\|$ which shows that the eigenvalues are bounded by $\|A\|$. The compactness of $A$ implies that the multiplicities of the eigenvalues are finite. It remains to show that the set of eigenvalues has no accumulation point different from zero. So assume that $\lambda = \lim \lambda_n$ is different from zero and the limit of a sequence of eigenvalues. We choose eigen vectors $a, a_n$ of norm 1.
Functional calculus for self adjoint operators

The spectrum $\sigma(A)$ of a bounded operator on a Banach space consists of all $\lambda \in \mathbb{C}$ such that $A - \lambda E$ is not a bounded isomorphism of Banach spaces. From the spectral theorem we derive the following three propositions (which in other approaches are proved directly and then the spectral theorem is a consequence of them).

2.5 Proposition. Let $A : H \rightarrow H$ be a self adjoint operator, then the spectrum $\sigma(A)$ is real and compact.

Proof. An argument with the geometric series shows that $B^*(H)$ is open in $B(H)$. This implies that the spectrum is closed.

For the rest of the proof we can assume that $A$ is a multiplication operator $m_f : L^2(X, dx) \rightarrow L^2(X, dx)$ where $f$ is a real, locally bounded function. Now, let $\lambda$ be a non-real number. Then $1/(f - \lambda)$ exists and is locally bounded. The same is true if $\lambda$ is a real number with $|\lambda| > \|\cdot\|_\infty$. Hence in both cases $\lambda$ is not in the spectrum.

Let $P \in \mathbb{C}[X]$ be a polynomial and let $A$ be an associative algebra with unit. Then $P(a) \in A$ can be defined for arbitrary $a \in A$ in an obvious way. In particular, one can define $P(A)$ for an endomorphism $A$ of a vector space. If $A$ is a self adjoint operator on a Hilbert space and if $P$ is real then $P(A)$ is self adjoint too.

2.6 Proposition. Let $A$ be a self adjoint operator and let $P \in \mathbb{C}[X]$ be a polynomial whose restriction to $\sigma(A)$ vanishes, then $P(A) = 0$.

There is an obvious conclusion.

2.7 Lemma. Let $A$ be a self adjoint operator such that its spectrum consists of one point $a \in \mathbb{R}$. Then $A$ is a multiple of the identity.

Proof. Consider $P(x) = x - a$. Then $P$ vanishes on the spectrum. This implies $P - a \text{id} = 0$.

2.8 Proposition. Let $A$ be a self adjoint operator and let $P \in \mathbb{C}[X]$ be a polynomial. Then we have

a) $\sigma(P(A)) = P(\sigma(A))$,

b) $\|P(A)\| = \|P\|_{\sigma(A)}$.

Here $\|P(A)\|$ means the operator norm and $\|P\|_{\sigma(A)}$ the maximum of $|P|$ on $\sigma(A)$.

The three propositions immediately imply what is called “functional calculus”.

121
2.9 Theorem. Let $A$ be a self adjoint operator. For each real continuous function $P$ on $\sigma(A)$ the bounded operator $P(A)$ can be defined in a unique way such that the following properties holds. The map
\[ \mathcal{C}(\sigma(A)) \rightarrow \mathcal{B}(H) \]
is a norm preserving Banach algebra homomorphism.

Additional Remark. Let $B$ be a bounded linear operator that commutes with $A$. Then $B$ commutes with all $P(A)$, $P \in \mathcal{C}(\sigma(A))$.

Let $A$ be a bounded linear operator on a Hilbert space. The commutator of $A$ consists of all bounded linear operators that commute with $A$. The bi-commutant consists of all bounded linear operators that commute with all operators of the commutator of $A$. Clearly $A \in \mathcal{G}(A)$. The Additional Remark in Theorem 2.9 shows that all $P(A)$ are in the bi-commutant of $A$.

2.10 Lemma. Let $A$ be a self adjoint operator on a Hilbert space $H$, Assume that the bi-commutant contains only operators whose kernel is $H$ or $0$. Then $A$ is a multiple of the identity.

Proof. We assume that $A$ is not a multiple of the identity. Then the spectrum consists of more than one point. Hence we can find two continuous real functions $f_1, f_2$ on the spectrum which are not zero but their product is zero. Let $A_i = f_i(A)$. These are two non-zero operators in the bi-commutant of $A$ with the property $A_1 \circ A_2 = 0$. This shows that $A_2(H)$ is in the kernel of $A_1$. So the kernel is neither 0 nor $H$. This proves the Lemma.

3. The von-Neumann bi-commutant theorem

Let $H$ be a Hilbert space and $\mathcal{B}(H)$ the algebra of bounded linear spaces. This is a Banach space with the operator norm and hence a topological space. But there are several other topologies. One of them is the strong operator topology (SOT) which is defined with the help of a family of seminorms. For each $a \in H$ we consider
\[ p_a(A) = \|Aa\|. \]
The SOT-topology on $\mathcal{B}(H)$ is the weakest topology such that these seminorms are continuous. It can be described concretely as follows. For $A \in \mathcal{B}(H)$ and $a \in H$ and for $\varepsilon > 0$ we denote by
\[ B_a(A, \varepsilon) = \{ B \in \mathcal{B}; \quad p_a(B - A) < \varepsilon \} \]
In the SOT-topology these sets are open and each open subset is the union of finite intersections
\[ B_{a_1}(A, \varepsilon_1) \cap \ldots \cap B_{a_n}(A, \varepsilon_n). \]
We have to consider sub-algebras \( A \subset B(H) \). The commutant
\[
A' = \{ B \in B(H); \quad AB = BA \text{ for all } A \in A \}
\]
is a subalgebra too. The bi-commutant \( A'' \) contains \( A \). We are mainly interested in star-subalgebras of \( B \). This means that with \( A \) also the adjoint operator \( A^* \) is contained in \( A \). The von-Neumann density theorem states.

3.1 Theorem (von Neumann bi-commutant theorem). Let \( A \) be a star-subalgebra of \( B(H) \) which contains the identity. Then \( A \) is SOT-dense in \( A'' \).

Proof. The proof rests on the following simple lemma.

3.2 Lemma. Let \( A \subset B(H) \) be a \( * \)-subalgebra and let \( P \in B(H) \) be a projector (i.e. \( P^2 = P \)). The space \( P(H) \) is invariant under \( A \) if and only if \( P \in A' \).

This theorem has an important consequence for unitary representations.

3.3 Theorem. Let \( \pi : G \to \text{Un}(H) \) be an irreducible unitary representation of a locally compact group. Then the image of \( C_c(G) \) in \( B(H) \) is SOT-dense in \( B(H) \).

Proof. Consider the SOT-closure \( A \) of the image of \( C_c(G) \) in \( B(H) \). This is a star-algebra in \( B(H) \). It contains then unity. By Schur’s lemma, the commutator \( A' \) of \( A \) consists of multiples of the identity only. Hence \( A'' = B(H) \) and we can apply the density theorem. \( \square \)

4. The Peter-Weyl theorem

Let \( K \) be a compact group and let \( \sigma : K \to \text{Un}(H) \) be a finite dimensional unitary representation. Recall that we defined the character
\[
\chi(x) = \chi_\sigma(x) = \text{tr}(\sigma(x))
\]
and a modified version
\[
e_\sigma = \dim(H)\chi(x).
\]
This a continuous function on \( K \). Unitary equivalent representations have the same character.

Other important functions on \( K \) are the matrix coefficients of an unitary representation \( \sigma \) (Here \( K \) needs not to be compact.) They are defined for two \( a, b \in H \) through
\[
\langle \sigma(k)a, b \rangle.
\]
The span a space of continuous functions that we denote by

\[ \mathcal{E}_\sigma \subset C(K). \]

In the case that the representation is finite dimensional one can choose an orthonormal basis \( e_i \) of \( H \). Then \( \mathcal{E}_\sigma \) is generated by the entries of the matrix

\[ \langle \sigma(k)e_i, e_j \rangle. \]

They satisfy the famous orthogonality relations.

4.1 Theorem. Let \( \sigma, \tau \) be two irreducible unitary representation of a compact group \( K \). Then the corresponding spaces \( \mathcal{E}_\sigma, \mathcal{E}_\tau \) are orthogonal.

Proof. Let \( \sigma, \tau \) be the two irreducible unitary (hence finite dimensional) representations. Let \( B : H_\sigma \to H_\tau \) be an linear map. Then we can build the operator

\[ A = \int_K \pi_\tau(k)B\pi_\sigma(k^{-1})dk. \]

Then the invariance of the Haar measure shows

\[ A\sigma(k) = \tau(k)A. \]

The operator \( A \) can not be injective, since otherwise it would be an isomorphism and \( \sigma \) and \( \tau \) would be equivalent. So the kernel of \( A \) is not trivial. But the formula above shows that the kernel of \( A \) is invariant under \( \sigma \). Hence it must be the whole space. So \( A \) is zero, whatever \( B \) might be. We will apply this for a well chosen \( B \). First we choose \( a \in H_\sigma, b \in H_\tau \). Then we define

\[ B(x) = \langle x, a \rangle b. \]

Then we choose two other vectors \( c \in H_\sigma, d \in H_\tau \). Then

\[ 0 = \langle Ac, d \rangle = \int_K \langle \tau(k^{-1})B\sigma(k^{-1})c, d \rangle dk = \int_K \langle \langle \sigma(k^{-1})c, a \rangle b, \tau(k^{-1})d \rangle dk = \int_K \langle \langle \sigma(k^{-1})c, a \rangle, \langle \tau(k^{-1})d, b \rangle \rangle dk. \]

This proves the theorem. \( \square \)

The space \( \mathcal{E} \) for a irreducible unitary representation is non-zero. It follows that there there are only finitely or countably many isomorphy classes of irreducible unitary representations of a compact group \( K \) (recall that we assume
§4. The Peter-Weyl theorem

that $K$ has countable topology and that the Hilbert spaces are assumed to be separable). Recall that we defined the unitary dual $\hat{G}$ to be the set of isomorphy classes of unitary irreducible representations.

We have introduced the convolution algebra $C(K)$. It depends on the choice of a Haar measure which we normalize such that the volume of $K$ is one. Recall that an unitary representation of $K$ can be extended to a representation $\pi : C(K) \to B(H)$. Now, let $\sigma : K \to GL(H_\sigma)$ be an irreducible unitary representation. Then we can consider the operator $\pi(e_\sigma)$.

4.2 Theorem. Let $\pi : C(K) \to B(H)$ be a unitary representation of the compact group $K$ and let $\sigma \in \hat{K}$. Then $\pi(e_\sigma)$ is the orthogonal projection of $H$ onto the isotypic component $H(\sigma)$.

4.3 Theorem. The functions $e_\sigma, \sigma \in \hat{K}$ satisfy the following relations.

$$e_\sigma * e_\sigma = e_\sigma, \quad e_\sigma * e_\tau = 0 \quad \text{for different } \sigma, \tau \in \hat{K}.$$ 

4.4 Theorem. Let $K$ be a compact group and let $f \in L^2(K)$. One has

$$\langle f, f \rangle = \sum_{\sigma \in \hat{K}} \dim(\sigma) \text{tr}(\sigma(f)\overline{\sigma(f)}).$$

This means of course that the sum is absolute convergent.

4.5 Theorem. Every irreducible unitary representation of a compact group $K$ occurs in the regular representation $L^2(K)$ and its multiplicity equals its dimension.
